Patient was comatose, cyanotic. Pupils at first dilated and then pinpoint. Pulse very weak. There were two scars on the lips and the entire mouth and tongue was whitened, on the chest and abdomen was very extensive burn, extending from the neck to the pubes. The treatment consisted of lavage with 10 per cent. alcohol and the introduction of yolk of eggs and sodium sulphate 5ii. Strychnin 1/20 gr. and digitalin 1/20 gr. were given hypodermically. The patient regained consciousness in two hours and was quite violent for a short time, then quieting down. The next day the urine was of the characteristic brown-black color sp. gr. 1005, for three days contained a few hyaline and granular casts; after this it was normal. The temperature remained slightly elevated for five days, 99 to 101.5. For two days there was some pain in the mouth, especially on swallowing. By the fifth day the mouth had cleared up, but the skin burn was still very sore, red and blistered. The patient was discharged well on the ninth day.

CASE 13.—Patient admitted 8 a. m. Sept. 14, 1905. Had taken carbolic acid 5i in water fifteen minutes before admission. Semi-conscious, cyanotic on admission. Burns on lips and tongue. Lavage with alcohol 10 per cent. Magnesia sulphate 5ii, two eggs and milk by tube. Strychnin 1/20 gr., digitalin 1/25 gr. hypodermically. Temperature 100, pulse 98; next day pulse and temperature normal. Discharged well September 16.

An analysis of the preceding cases shows several interesting features. The local effect on the mouth is greater if the acid is taken pure or in water than if taken in alcohol, all ten cases of the first class showing local eschars, whereas two of the three of the latter class showed no burns whatever. All the cases were unconscious on admission, except two who had taken the drug after drinking whisky and one who had taken it in water. This includes the cases which had taken the poison in whisky and beer. The longest period of unconsciousness occurred in the patient who had taken the acid in beer. The average period of unconsciousness of the cases having taken the drug in alcohol was three and three-quarters hours and of those in which no such history was obtained was one and three-quarters hours.

The mortality record was low, only two of the thirteen cases having died, one of these from bronchopneumonia a few days afterward, probably due to an inhalation of material during the lavage, which was performed with difficulty, and the other having been admitted moribund after having been kept for two hours outside without treatment. The treatment in all the cases consisted in a most thorough lavage with 10 per cent. alcohol and in the later few cases this was followed by lavage with plain water. In eleven of the cases milk and eggs were introduced through the tube and left in the stomach. Sodium sulphate was administered through the tube in three cases and intravenously in three cases and magnesium sulphate in the stomach in four cases. Stimulation with strychnin and digitalin was resorted to in eight cases.

CASES TREATED WITHOUT ALCOHOL.

A study of the records of the fourteen cases of carbolie acid poisoning treated at the Lakeside Hospital previous to the introduction of the use of alcohol in treatment surprised the authors by their similarity to their own results. In this series of fourteen, all of which were treated by thorough lavage, either with plain water or a solution of magnesium sulphate, there were only three deaths, two of these due to pneumonia and the third a case admitted ten hours after taking two ounces of the acid, an emetic of magnesium sulphate having been resorted to, but no lavage performed. In this early series also the cases which had taken the poison in alcoholic beverages seemed to show a greater tendency to unconsciousness than those that had taken it pure or in water. In the ten cases in which the record was made as to the manner in which it was taken, five took it with alcohol and five either pure or in water. Of the five alcoholic cases four were unconscious and one semi-conscious, while of the five that had not used alcohol two were unconscious, one semi-conscious and two conscious.

CASES COLLECTED FROM THE LITERATURE.

The following cases have been collected from literature, and though many of the reports are too meager for any conclusions to be drawn from them, they are inserted that the reader may see the various ways in which alcohol has been used in carbolie acid poisoning in recent years. It will be noticed that they are all of isolated cases.

In these cases the following abbreviations will be used:

S. and A. Sex and age.

P. Amount of poison and how administered.

T. Time elapsed before treatment.

L. Local eschars.

Sy. Symptoms.

Tr. Treatment.

C. Time elapsed before consciousness returned.

A. After history.

R. Results.

CASE 1.—Fraser,⁸ 1895. S. female. R. phenol, 3i, in whisky. T. 15 min. L. none. Sy. coma. Tr. atropin hypo, lavage. C. 8 hours. A. vomited 24 hours. R. well.

CASE 2.—Buchanan,⁹ 1899. S. and A. female, 35. P. phenol, 3i. T. short. Tr. sodium sulphate hypodermic, lavage with 2 quarts of 35 per cent. alcohol. R. well.

CASE 3.—Adams,⁸ 1899. S. and A. female, 36. Tr. alcohol 1 pint, by mouth; alcohol, 3iv, and whisky, 3iv, q. 15 min. Six doses whisky, 3ii q. h. 8 doses. R. well.

CASE 4.—Kelly, 1899. A. 21 months. P. phenol, 3i. T. 6 min. Tr. olive oil. Alcohol, 3vi. Apomorphin, 1/30 gr. Whisky, 5i, q. 10 min. Eight doses. C. 30 min. R. well.

CASE 5.—Klein,⁹ 1900. S. and A. female, 29. P. phenol,

3ii. Tr. alcohol, 3iv, by mouth q. ½ hours, 4 doses, then 3i q. i hour, 4 doses. Morphia, ¼ gr. R. well.

CASE 6.—Rodman,¹⁰ 1900. S. and A. female, 60. P. phenol, 3ii, pure. T. short. L. lips and tongue. Sy. coma, cyanosis, subnormal temperature. Tr. alcohol, 3iv, into pharynx, then lavage with warm water and then with dilute alcohol. A. temperature for 2 days, 101 to 102. R. well.

CASE 7.—Pinkney,⁹ 1901. S. and A. female, 3½ years. P. phenol, 3iv. T. ½ hour. L. lips and chin. Sy. coma, cyanosis, thready pulse. Tr. alcohol, 3iiiss. Strychnin, hypodermic, 1/30 gr. Infusion normal saline, 1 pint. C. 7 hours. A. temperature rose rapidly to 106. R. death in 12 hours.

CASE 8.—Gries,¹¹ 1901. S. and A. female, 3. Sy. coma, weak pulse, cyanosis, appeared moribund. Tr. Hypodermic of ether. Magnesium sulphate, 1½ quarts, by stomach tube, then lavage with 20 per cent. whisky and 3iv left in. Atropin, 1, 200 gr. Strychnin, 1/40 gr., hypodermic. C. few hours. R. well.

CASE 9.—McDonald,¹² 1902. P. phenol, 3i. T. 25 min. Sy. collapse, coma. Tr. stomach tube, alcohol, 6i left in a few minutes and siphoned off. This repeated once. Then lavage with water, whisky, 3iv, nitroglycerin, 1/100 gr., strychnin, 1/20. C. six hours. R. well.

CASE 10.—King,¹³ 1902. S. and A. female, 33. P. phenol, 3ss. 3 min. Tr. alcohol, 0ss. Then lavage with water, repeated. Alcohol, 3iii, left in. C. 4 hours. R. well.

CASE 11.—Marshall,¹⁴ 1903. S. and A. male, 74. P. phenol, 3i, and olive oil, 3iv, per rectum. T. immediate. Sy. coma, pulseless. Tr. irrigation with 2 quarts of water 1 hour and 10 minutes. Alcohol and water, aā3iv, repeated and irrigated. C. 8 hours. R. well.

CASE 12.—Atwell,¹⁵ 1903. S. and A. female, 35. P. phenol, 3ss, in water. T. 20 min. Sy. coma, cyanosis, weak pulse. Tr. atropin, 1/50 gr., hypodermic. Dilute alcohol, 3vi. Lavage with water, gallon 1. Alcohol, 95 per cent., 3vi. Lavage in 5 minutes. Magnesium sulphate, 3i, in water 6i. Stimulation. Infusion normal saline. R. well.

These two facts shown by a study of our own cases, namely, the immaterial difference in the mortality, whether the stomach was washed with alcohol or with some other liquid, and the apparently greater constitutional symptoms when the drug was taken with alcohol than when taken clear or in water, seemed to throw such grave doubts on the antidotal power of alcohol to carbolie acid when taken internally, and these doubts agreeing so well with the opinions expressed in the recent textbooks on toxicology, the authors determined before publication to undertake some experimental work in the effort to prove or disprove the antidotal action.

3. EXPERIMENTAL DATA.

BY DRs. BROWN AND CLARKE.

Acting under the direction of Dr. Torald Sollmann, a series of animal experiments were carried on in the pharmacological laboratory of the Western Reserve University, the results of which are herewith published.

INTRODUCTION.

Some experimental investigations of the subject have been undertaken by others, but these are rather unsatisfactory; the number of animals used by each investigator seems rather too limited to make the conclusions binding.

In 1901 Thornton¹⁶ made some experiments on a series of five dogs, giving by stomach from one to four

drams of phenol, undiluted, or with alcohol or oil. This was left in the stomach, together with the antidote. He gave to one animal phenol mixed with 95 per cent. alcohol, and after the onset of toxic symptoms administered more alcohol. The result was death in four hours, with no signs of improvement. Another animal was given phenol mixed with oil, which gave practically the same result. In the remaining animals phenol was administered and, after the poison symptoms had become manifest, alcohol in single or repeated doses was given without any beneficial effect.

The following year Wallace¹⁷ made observations on two rabbits and two cats. The first rabbit was given the lethal dose (0.6 gm. per kilo) subcutaneously, resulting in death in one hour and ten minutes. The second rabbit was given 5 cc. of 60 per cent. alcohol subcutaneously and this followed five minutes later by the same dose of phenol as was given the other rabbit. The toxic symptoms appear after the same interval of time as in the first rabbit. Five cc. doses of the diluted alcohol were injected at intervals, without improvement of the condition. The animal died in one and one-fourth hours.

The cats were given the lethal dose by stomach, one receiving the aqueous solution and the other receiving the phenol in 60 per cent. alcohol. Alcohol was later injected subcutaneously, but without effect. Both animals died after nine hours.

Fig. 1.—Intravenous injections of 1 c.c. per kilo of 1 per cent. phenol in normal saline at A, B and C. Time marks 15 seconds.

Method of Investigation.—Our experiments may be divided into three groups:

1. Systemic antagonism (intravenous injection).
2. Antagonism in the stomach (5 per cent. phenol).
3. Efficiency of lavage (undiluted phenol).

I. SYSTEMIC ANTAGONISM.

For the purpose of determining whether alcohol can lessen or abolish the systemic effects of phenol, a 1 per cent. solution was injected intravenously into dogs, the dose of 1 c.c. per kilogram (0.01 gm. of phenol) being repeated every minute. Three solutions of phenol were employed—one in normal saline solution, the second in 10 per cent. alcohol, and the third in 20 per cent. alcohol, the results produced by these solutions being compared.

Operative Methods.—All dogs used in these experiments were first given sufficient morphin to render them quiet and then kept under complete ether anesthesia during the course of the experiment. Before coming out of the anesthetic condition they were killed.

A cannula was placed in the trachea, through which the anesthetic (ether) was afterward given, and a cannula in the carotid for blood pressure tracings. The intravenous injections were made through a cannula placed in the femoral vein and connected with a graduated burette which contained the injection solutions.

(A) *Effects of Phenol in Normal Saline.* These will be described first for the purpose of comparison.

Blood pressure, and in some cases respiratory tracings, were taken. In all the animals the intravenous injection causes a fall of blood pressure which has a tendency toward recovery, depending on the quantity injected (Fig. 1.) Th. Gies¹⁸ obtained the same results in his experiment with animals. The average fall is from 20 to 30 mm. of mercury. The fall begins almost immediately after the injection; reaches the minimum in thirty seconds and returns to about normal after sixty seconds. Each successive injection becomes less effective, with a tendency toward a slow gradual fall of blood pressure. Where the lethal dose is injected there is a rapid fall which terminates by stoppage of the heart (Fig. 2.).

Respiration is but little affected except by the mechanical interference of the convulsive movements.

Onset of Convulsive Movements.—In all the animals employed the intravenous injection causes a gradual onset of convulsive movements beginning with a tremor of the legs and jaw, which gradually increases until the contractions acquire a clonic convulsive character. The absence of a rise of blood pressure which is usually associated with convulsions is probably due to the deep anesthesia and to the rather mild type of the convulsions.

(B) *Effects of Alcoholic Solutions of Phenol.*—

Fig. 2.—Death from intravenous injection of phenol. Injection made at A.

These do not differ from those of the saline solution of phenol in either quality or quantity. This is shown by Table 1.

TABLE 1.—INTRAVENOUS INJECTION. (Dog).

Dog No.	Solvent.	Fall of Blood Pr. after first injection.	Twitching movements after c.c. per kilo.
1	Normal saline...	30 mm.	5 c.c.
4	Normal saline...	40 mm.	5 c.c.
2	10 p.c. alcohol...	24 mm.	3 c.c.
3	20 p.c. alcohol...	40 mm.	5 c.c.

II. ANTAGONISM IN THE STOMACH.

To determine the possibility of an antagonism in the stomach, the phenol was administered by stomach tube to rabbits. The just fatal dose (0.6 gm. per kilo.) was given, as a 5 per cent. solution in water, and in 10 per cent. alcohol and in 10 per cent. glycerin. These animals were not anesthetized.

(A) *Effects of the Watery Solution.*—The first symptoms start in one to three minutes and consist in a general trembling of the body and legs. The legs grow weaker and the animal falls on its side. Convulsive movements of a clonic type then appear, varying somewhat in intensity; the legs may become extended and rigid, while in some cases the head is thrown backward. Death occurs in from twenty-six minutes to six days.

The alcoholic and glycerin solutions produced the same effect quantitatively and qualitatively. This is shown in Tables 2 and 3.

TABLE 2.—DETAILS OF STOMACH EXPERIMENTS ON RABBITS.

Rabbit No.	Weight in (lbs.)	Amount of Phenol Given (always 0.6 gm. per kilo.)	Diluent used.	Time Elapsed Before Appearance of Convulsive Movements.	Final Result.
7	920	11	Water.	1 m. 45 sec.	Died after 28 min.
7	770	..	Water.	Tube passed into trachea.
8	490	5.5	Water.	1 m. 30 sec.	Died after 25 min.
9	980	11.7	Water.	1 m. 30 sec.	Died after 9 days.
10	770	9.2	Water.	2 m. 10 sec.	Died after 8 hrs.
3	870	10.4	10 p. c. alc.	1 m. 50 sec.	Died after 24 hrs.
5	920	11	10 p. c. alc.	6 m. 30 sec.	Died after 3 hrs.
12	750	8.7	10 p. c. alc.	3 m. 15 sec.	Died after 18 min.
13	670	8	10 p. c. alc.	2 m. 20 sec.	Died after 2½ hrs
2	830	10	10 p. c. glyce.	1 m. 40 sec.	Died after 3½ m.
4	1450	17.5	10 p. c. glyce.	2 m. 45 sec.	Survived.
16	1200	14.4	10 p. c. glyce.	3 m. 30 sec.	Survived.
11	780	9.3	10 p. c. glyce.	2 m. 10 sec.	Died after 2 days.

* It was thought some of the solution was aspirated into the trachea in this animal.

TABLE NO. 3.

TIME OF DEATH IN STOMACH EXPERIMENTS. (Rabbits.)

Phenol dissolved in	
Water.....	25 minutes.....38 minutes.....8 hours.....6 days
Alcohol.....	18 minutes.....2½ hours.....24 hours.....3 days
Glycerin.....	32 minutes.....2 days.....Survived.....Survived.

Microscopical Examination of the Stomachs.—This was undertaken by Dr. W. W. Williams in rabbits 1, 2, 3, 8 and 12. The findings may be arranged, according to the severity of the lesions, as follows:

Rabbit No.	Lesion.	Medium in Which Phenol was Administered.	Time Elapsing Before Death.
1	None	Water	28 minutes.
8	Very slight	Water	25 minutes.
3	Fairly marked	Glycerin	3½ minutes.
5	Very severe.	Alcohol	24 hours.
12	Very severe chronic gastritis (probably not due to the drug).	Alcohol	18 minutes.

It is seen that the local lesions are quite as severe with the glycerin or alcoholic solution as they are with the watery solution.

From these results it is evident that the alcoholic solution is no less toxic than the aqueous solution; while

washings returned clear. One c.c. per kilo. of 95 per cent. phenol was then introduced through the tube and allowed to remain for ten minutes, when lavage was started, either with water or with 10 per cent. alcohol.

(A) *Effects of Concentrated Phenol by Stomach Without Lavage.*—This was tested on one animal. This showed an immediate fall of blood pressure amounting to 40 mm. of mercury. The pressure remains about constant after this primary fall, with a tendency toward a slight gradual fall, which continues until death. At no time during the experiment was there any evidence of improvement in the condition.

(B) *Lavage.*—In those animals in which lavage is employed, the blood pressure begins to rise after an interval of time which varies with different animals. The convulsive movements cease and the animals show all signs of recovery, the condition being judged by the blood pressure and convulsive movements.

The results are shown in Figure 3. They are identical for all the experiments, whether water or alcohol was used for lavage.

The details of the experiments are shown in Table 4.

4. THE LOCAL ANTAGONISM OF CARBOLIC ACID AND ALCOHOL, AND OTHER PHENOL-SOLVENTS.¹⁹

It will be recalled that the employment of alcohol in phenol poisoning was originally based on the local antagonism of the two drugs. This antagonism, as is well known, can be easily demonstrated, by dipping the finger in carbolic acid and then washing it at once with strong alcohol. To secure a complete removal of the phenol effects, however, it is essential that the application of the phenol should be of short duration, and followed very quickly by the alcohol. This is illustrated by the experiments of Wallace.¹⁷ For instance, when the alcohol was used immediately, it removed all the effects completely; when it was used after ten minutes it removed the superficial whitening of the skin, but not the deep effects. When it was used after thirty minutes it had almost no effect. The addition of a small quantity of alcohol to the phenol increases its local effects—an obser-

7 3	3	Alcohol.	10m	89	30	Until death	20	At death.	16 minutes.	Died.	Tube did not enter stomach in washing.

the glycerin solution appears to be rather less fatal than the others, since two of the animals recovered completely. This might be due to slower absorption; for we are loathe to attribute it to any antidotal properties, either chemical or physiologic.

III. EFFICIENCY OF LAVAGE.

To determine the effect of lavage after the administration of concentrated phenol, and the relative value of water and diluted alcohol for this purpose, we employed dogs, anesthetized with morphin and ether, and connected for blood-pressure tracings. A stomach-tube was inserted and the stomach washed with water until the

vation which effectually refutes the theory that alcohol and carbolic acid enter into an innocuous chemical combination. The increased effect is to be explained by a more rapid absorption of the slightly diluted acid.

Wallace attributes the antagonism to the solvent action of alcohol on the phenol which would remove it much more readily from the superficial layers of the skin than would water. If the theory be correct, other phenol solvents must produce the same effect as alcohol. Wallace tested this with chloroform, ether and benzol, with positive results.

19. This chapter was kindly furnished by Prof. T. Sollmann, by whom the experiments were performed.

We made the following experiments, using somewhat different solvents:²⁰

EXPERIMENT 1.—(a) The finger tips are plunged for thirty seconds into liquefied (95 per cent.) phenol, then for five minutes into the solvents. At the end of this time the finger in water is blanched, the fingers in 50 per cent. alcohol, 50 per cent. glycerin, ether and cottonseed oil appear normal. (b) The fingers are again dipped in the carbolic acid for one minute, then for one minute in the solvents.

The blanching is very conspicuous in water; then follows the 50 per cent. glycerin, then the 50 per cent. alcohol and ether.

The sensory effects are greatest in water, ether and 50 per cent. alcohol; less in 50 per cent. glycerin and oil.

EXPERIMENT 2.—The fingers are dipped into liquid carbolic acid for one and one-half minutes, then into solvents and observed at end of (a) one minute, (b) two and three minutes.

(a) One minute in solvents: The blanching is by far the most conspicuous in water; then follows the 25 per cent. glycerin and 25 per cent. alcohol. Turpentine and cottonseed

effect is mainly due to solution and is not chemical. The solvents also tend to lessen the burning sensation, probably by removal of the phenol. They appear to be quite unable to prevent the late effects of the phenol, which may be attributed to the phenol which had already penetrated deeply when the solvent was applied.

It appeared interesting to determine also whether these solvents exert any effect when the carbolic acid is left in contact with the skin. For this purpose 5 per cent. solutions of phenol were made in various solvents. These were arranged in five small beakers, so that all the fingers of the left hand could be inserted and withdrawn simultaneously. The degree of blanching, tingling and anesthesia was compared after five minutes. The tingling sensation proved to be too irregular to be of any value for comparison. As in the previous series, the nature of the solvents were unknown to the experimenter and compiler until the conclusions had been drawn.

Fig. 3.—One c.c. per kilo of 95 per cent. phenol introduced into the stomach at A, time 10:25. Regan lavage at B, time, 10:35, finished lavage at C. Blood pressure at end of experiment 100, time, 2:55. Base line corresponds to 0 pressure.

oil appear normal. Burning is felt in the water, and in the glycerin and alcohol solutions, not in turpentine and oil. The water finger also shows the greatest anesthesia.

(b) Two or three minutes in solvents: The blanching is most pronounced in the water; then follows 25 per cent. glycerin, then 25 per cent. alcohol. None is seen in turpentine and oil.

(c) The finger which had been put in water and which was still very much whitened, is rinsed in 95 per cent. alcohol. The blanching disappears almost completely at once.

(d) On the following day the skin of the fingers is rough and broken, and this condition persists for several days. It is alike in all the fingers.

It may be concluded that all phenol solvents arrest the local action of the phenol, i. e., the blanching action.

This and the observation that dilution of the alcohol greatly impairs its efficiency sufficiently show that the

EXPERIMENT 3.—Comparison of 5 per cent. phenol in water (W), 10 per cent. alcohol (A), 10 per cent. glycerin (G), and cottonseed oil (O).

Experiments on two persons gave identical results:

The anesthesia was most conspicuous in W; somewhat less in A, absent in G and O.

The blanching was marked and about equal in W and A, almost absent in G, quite absent in O.

EXPERIMENT 4.—Comparison of 5 per cent. phenol in water, 25 per cent. alcohol, 25 per cent. glycerin, turpentine and cottonseed oil. The experiment was repeated on nine persons, with the following results:

anesthesia.	Most Marked.	Less Marked.	Absent.
Water	2 cases	1 case	1 case.
Alcohol	2 cases	3 cases	1 case.
Glycerin	None	1 case	8 cases.
Turpentine & Oil	None	None	9 cases.

²⁰ In all the experiments the subject was not aware of the nature of the solvent, the containers being numbered and the results tabulated by these numbers.

BLANCHING

	Most Marked.	Second Place.	Third Place.	Fourth Place.	Absent.
Water	9 cases	None	None	None	None
Alcohol	None	5 cases	2 cases	None	2 cases
Glycerin	None	3 cases	3 cases	None	3 cases
Turpentine	None	None	2 cases	3 cases	4 cases
Oil	None	None	None	None	9 cases

TINGLING.

	Most Marked.	Second Place.	Third Place.	Absent.
Water	1 case	None	None	8 cases
Alcohol	3 cases	None	None	6 cases
Glycerin	None	1 case	None	8 cases
Turpentine	None	None	None	9 cases
Oil	1 case	None	1 case	7 cases

These results show that the addition of all the solvents diminishes the local effects of phenol. The effect on the tingling sensation is, however, irregular. This may be attributed to the difficulty of exact observation. The effect is more pronounced on the superficial action (blanching) than on the deeper actions (anesthesia). Oil alone prevents both actions in all cases. Then come, in order of efficiency, turpentine, 25 per cent. glycerin, and 25 per cent. alcohol. Glycerin is more effective, for the same degree of dilution, than is alcohol.

In this experimental arrangement the effect of the solvents can not be explained, as in the previous series, by removal of the phenol. Nevertheless, it seems to be connected with their solvent power. It may be explained in the following manner: If a substance is introduced into a mixture of two immiscible solvents, a and b, it will be distributed between these two solvents in a ratio proportional to its solubility in a and b. If it is more soluble in a, this will contain a greater amount. This may be demonstrated by shaking a 1 per cent. solution with an equal volume of olive oil in one test tube, and with an equal volume of petroleum benzin in another. If a little ferric chlorid solution is added to both test tubes, the watery layer will not be colored in the oil tube (the phenol having passed into the better solvent), while it will be colored a deep violet in the benzin tube. The benzin being a poor solvent, almost all of the phenol has remained in the water.

In our experiment, the fluids of the tissues constitute one solvent, the fluid in which the carbolic acid is applied the other. The better the solvent power of our solvent, the less of the carbolic acid will pass into the tissues.

In the case of alcohol, and to a lesser extent with glycerin solutions, some of the solvent is doubtless absorbed into the tissues, which explains the relative inferiority of these to turpentine, and especially to oil, which are absorbed much more slowly.

These experiments contradict the rather prevalent opinion that the absorption of phenol is quickened by alcohol and perhaps also by glycerin. As far as we know, this opinion is purely theoretical. It may be true as far as the addition of small quantities of these substances are concerned, which would then act, not so much as solvents, but by increasing the fluidity of the phenol—a very important factor in absorption. It might theoretically hold also for the alimentary canal, since these solvents are absorbed there with considerable rapidity. This view is supported by the clinical experiences, although our experiments on rabbits (Series 2) can scarcely be interpreted in its favor. As concerns the skin, the experimental results constitute a positive refutation of the quicker absorption of alcoholic solutions in this situation.

The relative inferiority of alcohol to the other solvents is not sufficient to be of importance; while its greater fluidity and its miscibility with water constitute practical advantages more than sufficient to counterbalance the theoretical deficiencies. In emergencies, however, the value of the other solvents, particularly oil, should be borne in mind. It is interesting to note that the use of the latter antidote preceded that of alcohol.

GENERAL CONCLUSIONS.

From the above experiments the following conclusions may be drawn:

1. Alcohol has a local antidotal effect to carbolic-acid burns, due to its solvent action.

2. There is no evidence of chemical antagonism between alcohol and phenol.

3. There is no effect produced by alcohol on carbolic-acid poisoning after the latter has been absorbed into the system, as is shown by the intravenous experiments on dogs.

4. Alcohol and phenol placed in the stomach give no different results from phenol alone.

5. Lavage with alcohol is effective when the phenol is in the stomach, but its superiority over lavage with water is not pronounced.

From the clinical aspect it appears that alcohol has a local antagonism to carbolic acid. When the latter is taken in whisky the feeling of discomfort is less marked, and the local eschar is absent or but slightly evident. In cases of poisoning, lavage with alcohol is apparently an effective method of treatment. This is borne out by a comparison of thirteen cases here reported with a mortality of 15 per cent., with the collection made by Falck²¹ in 1868 of forty-six cases in which the acid was taken internally with thirty-five deaths, a mortality of 65 per cent. On the other hand, the fourteen cases treated at the Lakeside Hospital by lavage prior to the use of alcohol with three deaths, a mortality of 21 per cent., give results so nearly akin to the alcohol cases that it would appear that the lavage were the dominant factor rather than the alcohol. When it is considered that it was only in the early nineties that stomach washing came into general use, and even later that the fear of its use in cases of corrosive poisoning was overcome, it seems probable that the good results in carbolic-acid poisoning from the use of alcohol, during the past few years, were due to the lavage and not to any antidotal property of the alcohol.

The authors do not wish to be interpreted as considering that alcohol is of no value in cases of carbolic-acid poisoning. *A priori* its solvent action and a slight tendency in the experiments with phenol in the dog's stomach, to an earlier rise in blood pressure, when the stomach is washed with an alcoholic solution, than when water is used, point to its value as a means of removing the poison from the stomach. From abundant clinical evidence, both in their own experience and in literature, it would appear to them to be an aid, when properly used, in the saving of life. On the other hand, this same solvent property, and the more marked symptoms of intoxication, when the poison has been taken in whisky, seem to establish a contradiction to the alcohol being used as an antidote and left in the stomach.

The procedure recommended is immediate, abundant lavage with 10 per cent. alcohol, this to be followed by lavage with plain water, and stimulation as indicated. The point to be borne in mind is that alcohol is not effective after the carbolic acid has been absorbed and, to

21. Falck: Ref. Blyth, Poisons. Their Effects and Detection. Wood's Library, 1885, p. 146.

be of value, must be used while the poison is still in the stomach.

The other common methods of treatment of phenol poisoning are now being investigated, and the results will be communicated later.

The fact that three of the five fatal cases in the Lakeside Hospital series died of pneumonia, and one, at least, of these of a definite bronchopneumonia of the inhalation type, has impressed the authors with the necessity of care in the method of performing lavage in this class of cases. With the patient lying on his back, in a comatose condition, with the gastric contents regurgitating around the outside of the stomach tube, it is a simple matter for material to enter the larynx and set up an inflammatory process in the lung. To overcome this danger, the authors recommend, immediately after the tube is passed, to turn the patient on his side or face, with the head low, thus allowing any fluid in the pharynx to escape through the mouth. Since this method has been used, there have been but few pulmonary signs during convalescence.

For his kindness in directing the work and for valuable suggestions and criticism, the authors wish to express their sincere thanks to Dr. Torald Sollmann.

TESTS FOR ACETONE IN THE URINE.*

ALONZO ENGLEBERT TAYLOR.

SAN FRANCISCO.

The interest of the surgical section of the medical profession is just now deeply concerned with the question of acetonuria. This interest has been awakened by observations of the frequent occurrence of the urinary acetone-complex following anesthesia and associated with a toxicosis that has been fatal in a number of instances. That acetone occurs frequently following anesthesia has been long known, and that it frequently occurs following the ingestion of many narcotics is equally well known. That the toxicosis is the result of the acetone-complex, that it is, in other words, an acid intoxication, is not demonstrated. On the contrary, it is much more probable that the toxicosis and the acetone-complex are fellow results of a widespread antolytic degeneration, of a ferment intoxication that has been in some unknown way inaugurated by the anesthetic or narcotic. It is known that many poisons act, in large part, by the inauguration of such autolyses, and this observation holds as well for narcotics as for phosphorus. At present acetone is held to be always derived in the body from the fats through the intermediary stages of *b*-oxy-butyric and diacetic acids, but it can not be denied that it might have other derivations. Chemically, acetone might be easily derived from glycerin through the intermediary stage of di-oxy-acetone, and other reactions that are feasible from the chemical point of view will be easily recalled. For the anesthetics, a second element enters into the discussion. The chemical relations of chloroform and ether as so close to acetone that it is probable that a certain amount of acetone may be formed in the body from these substances. We have to deal, therefore, with a derivation of acetone from the fats of the body under the influence of a toxic autolysis; and a derivation of acetone of purely chemical nature from the anesthetic. Whether or not acetone occurs in the urine following every administration of chloroform is not known; in the published researches reliable meth-

ods have not been used. Certain it is that acetonuria is now being diagnosed by unreliable tests.

For several years I have tested nearly all the urines that have come under my notice with the different tests for acetone, and have also had a large class experience with mixed urines. These experiences have taught us that the commonly used tests for acetone are quite valueless, in that they yield positive results with urines free of acetone in the practical sense. There are two really good tests for acetone, those of Stock and of Denigès. Both these tests have been repeatedly recommended for clinical use, but for some inexplicable reason they have not been employed to any extent by clinicians. The test of Stock is a particularly reliable one, because it is a test for ketones and is not given by alcohols and aldehyds. It is very simple and rapid in execution. One must use for it the distillate of the urine. This, it must be insisted on, must be the rule for all tests for acetone. In classroom work we use from 50 to 100 c.c. of urine, which is made acid by the addition of a few drops of either acetic, hydrochloric or sulphuric acids. The first 10 c.c. of distillate will contain nearly all the possible acetone. For the use of the older tests for acetone (the iodoform, the mercuric oxid and the sodium nitroprussid tests), the distillate must be subjected to a second distillation; for the Stock and Denigès tests, however, this is not necessary. About an inch of the distillate is placed in a test-tube, a drop or two of a 10 per cent. solution of hydroxylamin hydrochlorid added (shaken), then a drop or two of a 5 per cent. solution of sodium hydroxid (shaken), then a couple of drops of pyridin (shaken), then about an inch of ether (shaken), bromin water is then added, drop by drop, with mixing until the ether layer becomes yellow, and then a few drops of strong hydrogen peroxid are added; if acetone be present, the ether will turn a distinctive green-blue. The test sounds a little formidable, but when the reagents are ranged in a row of dropping bottles, it is very simple. The test is not very delicate; for example, I have never seen a positive test in a normal urine of a person on a diet of not over 100 grams of fat *per diem*, though we know that all urines contain a faint trace of acetone. The test is very elective, and for practical work the lack of a greater sensitiveness is an advantage. The test of Denigès is quite as easily carried out. About an inch of the distillate in a test-tube is mixed with an equal amount of a solution of the subsulphate of mercury (mercuric oxid 50, sulphuric acid 200, water up to 1,000) and the mixture allowed to simmer (best stoppered) for about five minutes. A white crystalline precipitation occurs on cooling, which is very distinctive in appearance. If acetone be present in excess, the test is less well given. If but a trace be present, a trace of sodium chlorid will aid the precipitation, but it must not be added in excess. This precipitate is not soluble in dilute hydrochloric acid.

These two tests agree. I have never seen the Stock test present without finding the Denigès test positive. In a few instances I have obtained faint reactions with the Denigès test when the Stock test was negative. Equally distinctive is the Bamberger test: the formation of crystals of *p*-nitro-phenyl-hydrazone-acetone on heating the distillate, acidulated with acetic acid, with *p*-nitro-phenyl-hydrazin. It is not a convenient test, however, since the crystals must be recrystallized from alcohol and their melting point determined.

It is a yearly experience in our classroom work that, with the mixed urine of the students, the iodoform reac-

*From the Hearst Laboratory of Pathology, University of California.

tion is quite regularly positive, the mercuric oxid and the sodium nitroprussid tests very often positive, and the tests of Stock, Denigès and Bamberger negative. I have often had the same experiments with individual urines, and, although it has been most often noted in cases in which the patients were on drugs of various kinds, I have often seen it in the urine of healthy persons not taking any drug. When acetone is present, the iodoform, mercuric oxid and the sodium nitroprussid tests are positive; the error is always on the other side, they yield positive results when acetone and diacetic acid are absent.

I have often found acetone to be present as indicated by the tests of Stock and Denigès, without a reaction for diacetic acid being obtainable. This latter substance is tested for as follows: The urine is acidulated with hydrochloric or sulphuric acid and then extracted with ether. The ether will contain other substances besides the diacetic acid and acetone, and may be purified, if desired, as follows: The ether is shaken with an alkaline water which will take up the acid. This solution is then acidulated and the diacetic acid removed by another extraction with ether. This ether is then shaken with a solution of ferric chlorid in water so dilute that the color is scarcely discernible; if diacetic acid be present, the diluted Burgundy-red color is developed in the water. This test has one known fallacy. If the urine contain an abundance of aromatic derivatives, such as phenol, salicylic acid, the coal-tar antipyretics and hypnotics, traces of these will pass into the etherial extract, even into the purified etherial extract. To rule these out, the reaction of Arnold may be employed. The ether is mixed with an alkaline water and the diacetic acid is thus gotten back into watery solution. Five c.c. of a freshly made 1 per cent. solution of p-amido-aceto-phenon in 2 per cent. hydrochloric acid are mixed with half the volume of a 1 per cent. sodium nitrite solution, a few cubic centimeters of the watery solution and then a drop of strong ammonia are added. Two or three cubic centimeters of this mixture are then added to some 15 c.c. of hydrochloric acid, 2 or 3 c.c. of chloroform are added and then two drops of a fresh solution of ferric chlorid. The test-tube is then slowly and repeatedly inverted, so as to permit a mixing without especial shaking. The chloroform turns a marine blue if diacetic acid be present, a darker blue if large amounts be present. For unknown reasons the test fails at times; this is due possibly to the presence of other substances that pass into the etherial extract. I have never seen diacetic acid present without acetone. Diacetic acid may be present without *h*-oxy-butyric acid, but I have never seen the *h*-oxy-butyric acid present without diacetic acid.

If acetone is to be tested for, it should be done with good methods, entirely apart from any questions of the value of the information sought or the pathogenesis of the acetone-complex. The tests of Stock (described in 1899) and of Denigès (described in 1898) are certain in their results and easy of execution, and should replace the fallacious tests with Lugol's solution, mercuric oxid and sodium nitroprussid.

Alcoholic Dementia.—Dr. C. L. Hamilton says that alcoholic dementia is generally the result of organic brain degeneration, due to the action of alcohol, and that as the mental symptoms are the result of structural degeneration they are usually permanent and not relieved by the discontinuance of the poison.—*Illinois Med. Jour.*

THE TREATMENT OF ABORTION.

H. J. BOLDT, M.D.

Professor of Gynecology in the New York Postgraduate Medical School; Gynecologist to St. Mark's Hospital; the German Poliklinik; the Post Graduate Hospital; Consulting Gynecologist to Beth Israel and the St. Vincent's Hospital.

NEW YORK.

Before entering on the consideration of this subject I wish to say a few words other than those concerning the treatment.

For practical purposes abortion may be defined as the interruption of gestation before viability of the child.

Physicians are not infrequently consulted as to whether or not the induction of an abortion is indicated in this or that case, and one must be very wary before giving an opinion, because the history given by the person asking for advice is often misleading. In heart disease, when there is dilatation with sufficient hypertrophy to compensate for the dilatation, the induction of an abortion should not be sanctioned. Neither is it indicated in psychical disturbances or in pulmonary diseases, except perhaps under exceptional circumstances. It is indicated, however, in pernicious hyperemesis and in some cases of chorea. In consultation with a prominent neurologist I saw one patient in whom convulsions occurred at frequent intervals, the patient not having been subject to epileptic seizures before pregnancy. They ceased after the uterus had been emptied. In nephritis the induction of abortion, in my opinion, is always indicated if the renal disease was present before the conception or if it manifests itself during the first three or four months of gestation.

In distorted or markedly contracted pelvis the patient should be permitted to decide for herself whether she wishes to go to term and be delivered by Cesarean section or whether she prefers to have an abortion induced. Due consideration should be given to each and all features connected with the individual case before the induction of an abortion is determined on, and it should never be undertaken unless it has also been sanctioned in consultation with another physician. If decided on the most favorable time for its induction is before the third or fourth month of gestation. Regarding the technic to be used in inducing an abortion, the well-known method with bougies has always proved itself the most reliable. If the bougie has not brought about the desired result in from twenty-four to forty-eight hours it may be supplanted with advantage with a tampon of a strip of nosophen (tetraiodo-phenolph-talein), iodoform or sterile gauze carried into and through the cervical canal into the uterus. As much gauze should be used as can be packed into the uterus without actually employing force. If carefully done there is no danger of rupturing the sac of the ovum. The precaution of the strictest asepsis or antisepsis in all details must be insisted on.

GENERAL TREATMENT.

The treatment of abortion may be divided into four parts:

1. Imminent abortion, in which there are signs pointing to the probable occurrence of an abortion, yet in which the symptoms may again subside on appropriate treatment.

2. Progressing abortion, in which the threatened abortion has further advanced so that its actual occurrence can not be prevented.

3. Incomplete abortion, in which a part of the prod-

ucts of conception has been expelled from the uterus, but some part is still retained therein.

4. Complete abortion, in which the ovum and its membranes have been completely expelled from the uterine cavity.

In imminent abortion the patients have either an occasional "spotting" of blood, or, at other times minimal bleeding; this is sometimes associated with an uneasy feeling in the lower abdomen, seldom also with slight expulsive pains. In the second class the patients have a more or less profuse hemorrhage, sometimes so profuse as to be dangerous. In this stage expulsive pains caused by uterine contractions are usually present; they may sometimes be absent, however. The bleeding may be constant or it may be at irregular intervals. This second stage is a continuance of the first division mentioned, and the ovum is still in the uterine cavity. The cervical canal in this stage may be contracted or it may be dilated or dilatable. In the third class the cervical canal may be either closed or dilated. The bleeding in this class varies in quantity and duration. It may continue only a few hours or it may last several days, and occasionally it may continue for weeks or even for months. It is usually dependent on retained particles of placenta if the bleeding is of long duration, or membranes or placental tissue in instances of short duration. In the fourth class the uterus has usually regained firmer consistence and the cervical canal is again contracted, but it may in some instances be dilatable. Sometimes quite free bleeding may still be present in this class of patients.

So far as the treatment of abortion is concerned, there is a unanimity of opinion as to the object to be attained in imminent abortion, but as to the progressing, incomplete and complete abortion there is a wide difference of opinion. I desire to give the views arrived at in more than twenty-six years of extensive personal experience with the different methods of treatment in vogue.

Before taking up the subject under separate heads permit me to consider it in a general way. It is understood that in cases of threatened abortion everything possible should be done to prevent the mishap. When, however, it is evident that the pregnancy can not be continued the uterus should be emptied at the earliest possible moment consistent with the greatest immediate and subsequent safety for the patient, and here opinions differ as to which method assures the greatest safety. It must be borne in mind that the treatment of abortion necessarily differs in its aspects in relation to safety according to the physician's surgical training and the surroundings of the patient. An intervention that would be safe in a well-conducted institution or in the homes of the wealthy, if performed by a man thoroughly educated in special work, would not be safe in a tenement house in the hands of an inexperienced physician. The object of my address is to express what I believe to be the safest treatment under all circumstances.

In the latter part of the seventies and in the early eighties, when active intervention was first recommended in instances of abortion, prominent specialists scorned those who would let Nature take her course, saying that they were too slow in keeping pace with progress. They advocated the invariable removal of the products of conception with instruments as soon as it was evident that abortion was inevitable. I, too, was then an obedient disciple of the teaching in favor of undelayed active intervention, but I have since modified my views because to a conscientious observer experience is an excellent teacher. Advocates of active intervention

in all cases of abortion take the position that patients who are treated by the expectant plan and allowed to abort spontaneously, after it is evident that the progress of the abortion can not be prevented, are in too much danger from hemorrhage and infection; that a better and more rapid involution of the uterus takes place if active measures are used; that there is less likelihood subsequently of endometritis, with perhaps the association of menorrhagic, metrorrhagia and irregular menstruation; less liability to abort again in the event of a future pregnancy; also less risk of sterility following the abortion. All these risks are avoided, they claim, if the patients who are in a stage of progressive abortion or who already have completely aborted were invariably curetted. The active intervention, it is claimed, is further of advantage because it is a great saving of time for the physician and the patient and is absolutely free from danger. I can admit only one part of all the advantages alleged for immediate intervention, namely, that of saving time. I also agree to the comparative freedom from danger if the attendant is a thoroughly trained man in that kind of work. Some recommend curetting always, even if the ovum and its adnexa have been expelled, for the purpose of completely removing the decidua vera and of making sure that no adherent particles of placenta remain; others, who modify somewhat that advice, believe and teach that it is necessary to curette only in cases of incomplete abortion. The result, especially in this country, is that the curette is used oftener than any other surgical instrument by family physicians, and curetting is thought by many to be a perfectly harmless and safe procedure. The carrying out in practice of such a view by so many physicians may be excusable if we consider that there are many whose teaching may be presumed to be from a fountain of authority who by sayings and writings taught many colleagues the necessity for curetting in abortion cases.

After seeing a very large number of infections and a number of accidents in the hands of physicians not so experienced in gynecologic techniques as they ought to be to undertake this kind of work successfully, and after keeping under protracted observation a large number of patients in hospital and in private practice, I gradually began to change my views, and the more I analyzed the more certain I became that I had been in error in my method of management of abortion cases.

Experience in obstetrics has shown that those patients do best with whom Nature is allowed to take her course and no intervention practiced unless there exists a positive indication for it.

While an abortion is a pathologic process in contradistinction to the physiologic process of labor, yet, so far as the necessity for surgical intervention in abortion is concerned, it should be restricted, just as in obstetric practice, to those cases in which there is an absolute indication for it. It would carry me too far to go into all the details as to why there exists such a difference between the pathologic process of abortion and the physiologic process of parturition; let it suffice to say that the principal reasons are to be found in the changes in the placenta and in the decidua during the latter period of pregnancy and in the greater contractile power of the uterus at the normal termination of gestation.

One need not worry about a possible future danger in the greater number of instances of abortion so long as the patient is kept clean, because Nature will take better care of an ovum and its adnexa or of retained remnants than we can with fingers or instruments. After most painstaking research I have been unable to confirm

the opinion which I formerly held regarding the detrimental effects previously spoken of; I have not found that patients who are treated without surgical intervention, that is, those in whom the interior of the uterus is not scraped with a curette, or with whom forcible manual removal of the conception products is not undertaken, are in worse health than those who were subjected to the aggressive surgical method. I have not observed that the retention of decidua in women who had previously enjoyed good health gave rise to any trouble during convalescence. Neither did such women seem more liable to endometritis or to subsequent sterility. It is true that the menses after an abortion, during the first one, two or three months, are somewhat more profuse than they were during former normal menstrual periods, yet this is not caused by the non-intervention; this condition is quite normal and frequently occurs after normal delivery. I do not wish to convey the idea, however, that artificial means to empty the uterus of conception products should be neglected when an indication therefor is present. When there is an elevation of temperature or evidence of decomposition of retained conception products, or in the event of profuse bleeding, it is necessary to resort to artificial means to empty the uterus.

If we do resort to intervention for the purpose of emptying the uterus it is preferable to accomplish this with a finger rather than to resort to a curette whenever it is possible thus to accomplish our object. The use of a curette is indicated only in those cases in which remnants can not be manually removed.

Sometimes difficulties are experienced in endeavoring to remove conception products manually, but these difficulties are experienced only when the local conditions are unfavorable for such intervention. Unless the index finger can be readily passed through the cervical canal and all parts of the uterine cavity explored, perseverance in attempts at the removal of the remaining parts of the placenta, membranes or fetus by manual manipulations is not advisable. It must be granted, however, that much depends on one's dexterity; it would not be logical to expect a physician who had had but little experience with gynecologic technic to possess the same ability as one who had had special training in this work and perhaps many years' experience. The manual removal of conception products is often difficult because of frequently recurring contractions of the cervix and because of the increased size of the uterus, so that it is difficult to get the finger up to the fundus.

The employment of a curette in a puerperal uterus is more or less risky because such a uterus does not offer the same amount of resistance to the rigid, unyielding instrument as the non-puerperal uterus, and consequently a perforation may occur even in the most skilled hands. The tactile sense of the finger, however, can always determine what it is doing in the uterine cavity. Another risk incurred when a sharp curette is used for the scraping is that the endometrium may be so deeply destroyed that subsequent atresia of the uterine cavity may result. Such women can not again become pregnant, and the menstrual function may cease entirely. I have seen several such cases.

If a perforation occurs in a non-infected uterus no harm is likely to result if the patient is immediately left alone and no further intrauterine manipulating done. If, however, the uterus is infected when the perforation occurs there is great danger of peritoneal infection. Further, there is danger of a loop of intestine coming through the perforation. I have seen one such

sad accident in the hands of a physician who had had considerable experience with this so-called trivial, but in reality, serious operation. Not only did the coil of bowel prolapse, but, still sadder, it was mistaken for the umbilical cord and torn. At the abdominal section, made by me, it was shown that the bowel had been deprived of its mesentery for about fourteen inches. A number of bowel accidents are on record as the result of curetting for the purpose of cleaning out conception products from a puerperal uterus. Profuse bleeding, and sometimes even alarming hemorrhage, may occur during the curetting of a puerperal uterus, and still the removal of all conception products is not assured.

Let us take for granted that an indication for the employment of a curette is present—and indications certainly do exist in some cases—what kind of an instrument should be selected? It is my opinion that a dull curette is useful only in those cases of abortion in which remnants of placenta are still in the uterus and inaccessible to the finger; then a large dull curette may be used to loosen them. I have not seen any cases in recent years, however, in which I found such an instrument necessary. Other treatment has proved itself more satisfactory and safer. If a curette be used at all, a large, broad, sharp curette is to be preferred, because no physical force is required to scrape over the interior of the uterus; a broad instrument is not so likely to cause a perforation as a narrow one, besides small adherent placental remnants are more likely to be removed by an instrument that covers a larger area.

SPECIAL TREATMENT.

Imminent abortion is best treated with absolute rest in bed and the internal administration of a narcotic like codein, giving doses of 0.03 to 0.05 (grs. $\frac{1}{2}$ to $\frac{3}{4}$) at intervals of one, two or three hours, according to circumstances, until from two to six doses have been taken. It may be possible that viburnum prunifolium is beneficial, but I have been unable to verify the claims made for it in the prevention of abortion when that drug alone was used. I believe that the first large dose of the narcotic and the absolute rest are the most important factors. Tampons and the preparations of ergot, or applications of ice bags, to stop the minimal bleeding sometimes present in these cases should be avoided, because these remedies may cause uterine contractions, and therefore are likely to bring about that which we are desirous of preventing. I have succeeded in preventing abortion several times after the fifth month of gestation when the cervix had been dilated to from one to two centimeters in diameter, and in one instance that is still quite vivid in my memory the dilatation had been advanced to about three centimeters. The finger could be readily passed through the cervical canal and could palpate the membranes, but no bleeding was present, yet after the administration of one-third of a grain of morphin subcutaneously, and three hours later three-quarters of a grain of codein, the expulsive pains, which had occurred at intervals of every hour or two for the previous half day, subsided and the patient went to term. Her pregnancy had advanced to the sixth month. In none of the patients alluded to had there been more than a minimal amount of bleeding; it was limited to a slight "spotting," so that one may, to some extent, be governed in giving a prognosis as to the possibility of preventing an abortion, even if the cervix is dilated or dilatable, by the amount and the character of the blood lost. For instance, in cases in which there was a dirty, quasi-grumous bloody discharge, although no marked

expulsive pains were present, and with a firmly contracted cervix, no matter what treatment was resorted to it had always been my misfortune to have the patients abort.

The consideration of progressing abortion and of incomplete abortion is the most important. Let us suppose a patient is bleeding and that the cervical canal is closed, the ovum and its adnexa still being in the uterus. The spontaneous expulsion may be aided by first giving a hot antiseptic vaginal douche and then tightly tamponing the vagina with iodoform gauze. The gauze acts as a hemostatic and also causes uterine contractions. In addition, an oxytocic should be administered internally. The gauze may remain in the vagina twenty-four hours, or, if the blood oozes through the gauze to any extent, it may be removed sooner and fresh gauze inserted more tightly. It is not at all unusual, however, to find that when the gauze is removed the entire ovum has been expelled and may then be found behind the gauze, or in further advanced pregnancy it may be that the embryo is expelled, while the rest of the uterine contents may still be in the lower part of the cervical canal, and the internal os may be again contracted above them, so that all may be readily removed with the fingers.

If the bleeding is not so profuse as to require more energetic immediate intervention, the patient may be ordered to lie perfectly quiet with the lower extremi-

washed, and the washing should be extended to the thighs and buttocks. After the washing with soap and water, all the parts should be washed with alcohol and then with an antiseptic solution. For the purpose of "scrubbing," a pad of sterile gauze or a ball of sterile absorbent cotton should be used. A brush is too rough for this purpose. After the cleansing of the patient and of the physician himself have been completed, it is advisable to surround the patient's thighs, etc., with sterile towels or a sterile sheet. The cervix should then be exposed with retractors or a speculum, and the gauze introduced.

An almost positive sign that the ovum has been expelled is the sudden cessation of expulsive pains, if they have been present previously. If the vaginal tampon is then removed, it is probable that the uterine tampon with the conception products has been expelled from the uterus. If this has been accomplished nothing further need be done; not even a vaginal douche need be given. The subsequent treatment is like that of an ordinary labor case; the external genitals must be clean and a sterile occlusion pad should be placed in front of the vulva and changed as often as may be necessary. It is always changed after each urination.

If a woman has been losing very much blood, so that more or less anemia has resulted, and if the bleeding is still continuous, it is not desirable to wait for the spontaneous expulsion by the treatment just described,

if the cervix is dilated to such extent that the interior of the uterus can be explored without using too much force in introducing the finger through the cervical canal. After the introduction of the finger, the removal of the uterine contents may be aided by compression of the fundus with the external hand; the intrauterine finger loosens the con-

ception products, and the patient should be requested to "bear down" as at child birth. To facilitate removal a placenta forceps (see illustration), which is a slight modification of the abortion forceps designed by Winter of Königsberg, may be used with advantage. With ordinary care there is no risk with such a forceps. The most accessible part is grasped without using so much compression as to separate the part held in the jaws of the instrument; with gentle rotary traction the part is extracted, and when sufficient is out of the external os the fingers are substituted and the extraction is completed with them. If it is thought necessary, the interior of the uterus may be examined with the finger, and if nothing further is detected this completes the work. No douche or tampon need be used if no evidence of infection has been present and if all the work has been done with the precautions described. The internal administration of ergot, however, is advisable. Two or three doses usually suffice.

If the bleeding is only moderate and the condition of the patient is good, that is, if there is no fever, then no intrauterine intervention should be resorted to, but another firm vaginal tampon should be inserted and oxytocics administered, the expulsion being relied on to take place spontaneously.

In patients with progressing abortion, but having no bleeding, either with a dilated or a contracted cervix, nothing should be done except to administer oxytocics, or the case may be entirely left to Nature unless indications arise which make intervention necessary.

Placenta Forceps.

ties closely adducted, which will cause the blood which flows into the vagina to form a clot, which acts as a hemostatic and also causes uterine contractions. Suppose, however, that the uterine contents have not been expelled when the gauze is changed, and the bleeding still continues, but that the cervical canal is dilated and the patient is entirely free from fever; then the safest plan is to take a sterile or, still better, a 2-inch bandage of nosophen (tetraiodo-phenolphthalein) gauze and tampon the uterine cavity with as much as can be introduced through the dilated cervical canal without using sufficient force to rupture the membranes. The upper part of the vagina is thus firmly tamponed and this will seldom, if ever, fail to incite uterine contractions of sufficient intensity to expel the ovum with or without the placenta and membranes. Usually everything is expelled.

It is understood that the strictest precautions should be used for the introduction of the intrauterine tampon. It should not be done with the patient in bed, only after washing off the vulva with some antiseptic solution. I have so frequently seen such erroneous procedure, supposed by the attending physician to be *secundum artem*, that I may be pardoned for referring to it in detail. The patient should be placed on a table or a couch which will permit of sufficiently good access to effect what should be done. After the thighs are flexed on the abdomen, the vagina should be thoroughly washed with green soap and hot water and a copious antiseptic vaginal douche given; the bladder should be empty. The external genitals should likewise be thoroughly

If the ovum and its adnexa have been expelled and there is still a continuance of bleeding and the cervix is contracted, the administration of ergot is indicated; whether it is given in the form of fluid extract or one of the other preparations of ergot, such as ergotole or ergotin, is a matter of personal choice; I have usually given the preference to Squibb's fluid extract if the patient did not object to the taste and if the stomach did not rebel against it. In patients in whom the uterus was not markedly enlarged and the cervix firmly contracted I have seen the most marked benefit from the administration of hydrochlorid of cotarnin (stypticin) in three-grain doses, given in capsules at intervals of three hours. The powder should be ordered to be put in a dry form into the capsules. Should the bleeding not cease from the administration of one of the remedies mentioned, curetting is indicated, with subsequent irrigation with a 1 per cent. carbolic acid solution. A similar procedure is indicated if the cervix is dilated under conditions above described.

Let us now consider the cases in which the embryo has been expelled, but in which the placenta is still in the uterus and the cervix contracted. In such instances, in the absence of fever, whether there is bleeding or not, we should treat the patient on the quasi-expectant plan and firmly tampon the vagina with iodoform gauze and administer ergot to bring about uterine contractions. I should not consider the necessity for more active intervention unless there was evidence of disintegration of the uterine contents. If the cervix is dilated, the uterus may be tamponed as previously described, or the placenta should be removed manually if it is not expelled spontaneously in twenty-four hours.

In that class of patients in whom the abortion is complete nothing at all should be done except to order rest in bed the same as after confinement. I believe the teaching that they should be curetted for the purpose of removing the decidua inadvisable.

It is obvious from what I have stated that I prefer to give the expectant plan of treatment the widest possible range, and I adhere strictly to it unless there are contraindications to it.

In instances of atypical bleeding, several weeks or months after a supposed complete abortion, one should not hesitate to examine the interior of the uterine cavity manually to ascertain whether the bleeding is caused by remnants of adherent placenta, a deciduoma or perhaps malignant growth, if a previous curetting and internal medication have been without effect. The cervix in such cases must be dilated to permit of the introduction of the examining finger. Usually steel dilators are made use of for this purpose, but some physicians prefer tents and still others use iodoform gauze. After having employed these several methods at different times for several years past, I have practiced dissection of the posterior cervical wall as the most satisfactory method of rendering the uterine cavity rapidly accessible to manual examination under the circumstances mentioned. It is quicker than any other method, and in my experience devoid of risk of subsequent infection, and it has otherwise no untoward consequences. The uterus is steadied with a double tenaculum forceps, one blade on each side of the median line; a scalpel, or a hysterotome, or a pair of scissors is used to split the posterior wall of the cervix, carrying the incision through the internal opening of the cervix, after which the uterine cavity will be found accessible to the average-sized index finger. By this method we have a smooth

and clean wound, and after examination it can be readily closed with a few interrupted chromicized catgut sutures. I have made a considerable number of intra-uterine examinations after having resorted to this procedure, and so far have never failed to get an absolutely satisfactory result.

Let us now consider those patients in whom there is evidence of infection. In such cases the uterus should be emptied as soon as possible, whether the cervix is dilated or contracted. If the latter is the case it should be dilated. I prefer for this purpose a branched steel dilator. An excellent instrument of this kind has been devised by my associate, Dr. A. Brothers. It gives an equal circumferential dilatation. It would be still better if the branches did not have so much spring. One should use a steel dilator with much discretion, in order not to tear the cervical structure. In a few instances I have used two rubber condoms, one inserted into the other so as to make it stronger, after the cervix had been sufficiently dilated to enable me to pass them through it. The end is firmly tied around the point of a Davidson's syringe, then the appliance is ballooned like a Barnes' bag dilator. This gives gradual dilatation without any risk of causing an abrasion. The only objection to this method of dilatation is that it is slower than the steel dilators. After there is sufficient dilatation the uterus should be cleaned out. If adherent particles are present they must be detached. If the entire cavity is not accessible, then a broad dull curette should be used. The uterus in these cases should be irrigated with three or four liters of a 1 per cent. carbolic acid or some other antiseptic solution. Intrauterine tamponade, in my opinion, is detrimental in all puerperal cases, because the drainage ascribed to it becomes illusory after the first few hours, and then it has a tendency to retard drainage instead of having the opposite effect, as is claimed for it.

If the abortion has taken place and one has reason to believe that there are only small remnants of adherent placenta retained, which give rise to the infection, and the cervix is not dilated, resort may be had to the curette without dilating to the extent spoken of; frequently no dilatation is required. A Martin curette or a strongly-built, broad irrigating curette answers best. I wish to repeat, however, that a curette should be used only when there is an absolute indication, and not on the slightest pretext, as has been done so frequently in the past and unfortunately is still being done. The curette has done much harm by causing deaths and prolonged illness, so that I can not lay too much stress on the objection to its injudicious use. The physician who employs it must be trained; it should never be used by any one inexperienced, especially in puerperal cases, because it is a dangerous instrument if improperly handled.

To go into details regarding the treatment of the septic infections following abortions would carry me too far. I will only allude to one other class, the most serious of all so far as life is concerned—sepsis in its severest forms following abortions, especially criminal abortions. Such cases tax the judgment of the most experienced to the utmost. Let me illustrate with only one example of the many patients that I have seen and operated on with varying results:

Patient.—M. S., was seen July 22, 1905, with Dr. George Doty. The patient was 20 years old and single.

History.—She had had a spontaneous abortion at about the second month of gestation, three days previously. When her physician first saw her the temperature was 99. When I saw her the temperature was 102.4 and pulse 90. There was

sensitiveness over the lower abdomen on pressure; the uterus was but slightly enlarged.

Treatment.—She was at once removed to a hospital, and the interior of the uterus explored with a curette because the cervix was too contracted for me to make a digital examination. A small quantity of retained material was removed. An extensive vaginal section was then made and the entire pelvis was packed with iodoform gauze, a procedure which I have found to be absolutely unsatisfactory in nearly every instance, despite the favorable reports emanating from other sources. (I presume this may be due to a difference in view as to what is a severe form of sepsis.)

Course of the Disease.—On the following morning her condition was much worse. On the afternoon of Sunday, July 23, the temperature had risen to 105 and the abdomen began to become somewhat distended. One severe chill and a rigor had occurred, and chilly sensations were constantly present. Although the coroner, who had been notified, had not yet put in an appearance, and in view of the fact that the patient's condition had been becoming worse from hour to hour, and from my previous experience I decided that to wait longer would be to lose time when there was still a chance to save life.

Operation.—At 5 o'clock, therefore, the patient was taken to the operating room and the abdomen opened from the umbilicus nearly down to the symphysis. Evidence of an acute septic peritonitis was present; the intestines throughout were inflamed and those of the pelvis were covered with lymph exudate. Some sero-purulent fluid was present in the lower abdomen. A pan-hysterectomy was done with removal of the adnexa, and the greater part of the broad ligaments was also extirpated. The abdomen was freely flushed with saline solution and the pelvis lightly tamponed with gauze, which was brought out into the vagina. On the following morning the temperature had dropped to 101 and the chilly sensations had entirely disappeared; the patient felt perfectly comfortable and was able to leave the hospital in excellent condition two weeks after her admission. From the third day on, however, she was out of bed.

Here we had evidently operated just in time; a day later, yes, perhaps only a few hours later, it would have been impossible to save life.

Such an example illustrates better than many pages of writing the difficulties one experiences in deciding what is the proper course to pursue with cases of severe sepsis following abortion. How often do we have patients whom we hope to save by less radical procedures until it is too late! If we operate early and the patient recovers, we rightfully ask ourselves whether the patient might not have recovered without such radical operation, or if she got well despite the operation? Such a query in the instance narrated, of course, can not be considered, because we had the objective proof in the intra-abdominal condition, and I have had similar proof in other cases, but, unfortunately, in the majority of such cases my patients have died, either because I operated too late or because the ailment had been too foudroyant from the beginning. Hence with patients having the severe forms of septic infection, patients with bacteremia from abortion or following labor at full term, we are placed in an unenviable position; we do not know by any definite landmark, if I may use that term, what decision we should come to to save life, so far as a major surgical intervention is concerned. Hence it is that from time to time we have varying opinions of a particular form of treatment. Examination of the blood for bacteria, which we hailed only a short time ago as the most important aid in helping us decide, has been found wanting in most of the instances that have come under my observation. The silver preparations of Credé and antistaphylococcus serum have been equally unsatisfactory in their therapeutic value in most of my severe cases. Once in a while, it is true, a patient recovers whom we

had reason to believe to be beyond recovery, but whether this is due to the alcoholic stimulation, which I believe should be generously employed in sepsis, or to one of the remedies used, or—and that seems more probable to me—to the inadequate amount of poison in the system of the patient and her strong vitality and ability to withstand that poison, is at present only a matter of speculation. In my opinion the future remedy will be a serum, which I hope may soon be discovered.

The guide which I have adopted for myself is best illustrated in the example cited. If a patient has no decomposing elements in the uterus to account for the infection, or even if she has, and there are reasons why they can not be satisfactorily removed, and if there is no exudate in the pelvis, so that the focus of infection seemingly is limited to the uterus, and such a patient is gradually becoming more ill, the offending organ should be removed ere it is too late. It may be possible that sometimes we may err in operating on a patient who might possibly have recovered without operation, but we can do no more than use our best judgment most conscientiously applied.

An exceedingly interesting feature from a pathologic viewpoint is that sometimes in the most virulent forms no evidence of micro-organisms in the uterus is reported by the pathologist. This, too, I may best illustrate by citing an example:

Patient.—A. B., aged 30, was seen in consultation July 18, 1905.

History.—She is the mother of four children, the last born eleven days previous to consultation. On the third day post-partum, her temperature was 102, pulse 84. Her physician then gave an intrauterine douche. Later chills occurred, and the patient also complained of pain in the right iliac fossa. The temperature varied from 103 to 105, the pulse from 110 to 120. The patient was delirious at times. The abdomen was not greatly distended, but it was sensitive to pressure. The uterus was much enlarged and relaxed in consistency. The diagnosis of puerperal sepsis, with probable diffuse septic peritonitis, was made.

Operation.—The physician in attendance and the relatives desired that an attempt be made to save life by operation, despite the fact that they were informed that such an attempt was almost useless. I finally consented with reluctance. The expected result occurred only sooner than was anticipated; the patient died on the table at the completion of the operation. Yet no micro-organisms were found. The diffuse septic peritonitis that was diagnosed was found to be present.

Examination of Organs.—Macroscopic Examination.—Uterus measures 9x7x6 cm. and has been laid open. Mucosa of canal necrotic looking. Ovaries normal size and fibrous, tubes normal.

Microscopic Examination.—Ovaries and tubes show chronic inflammation. Wall of uterus shows scattered groups of round cells. These small abscesses extend all through the uterine wall, but sections stained by Gram's method do not show any collections of cocci. Scattered here and there are occasional round bodies, which look like cocci. Mucosa appears to be replaced by necrotic tissue.

Diagnosis.—Acute metritis. Chronic salpingo-oöphoritis.

I have several times received negative reports in such cases, so that I should be glad to be enlightened on this.

39 East Sixty-first Street.

A Definition of Urethral Stricture.—MacGowan defines stricture as a lessening of the normal caliber and interference with the dilatability of a urethral canal by round-celled infiltration, or deposit within its walls or in the corpus spongiosum of ectriathral connective tissue as a result of prolonged or chronic inflammation, or mechanical or chemical injury.—*American Journal of Urology.*

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XII.

ASTRINGENTS.

Astringents are substances which produce a constriction of all the solid tissues with which they are brought into intimate contact. All substances that are capable of forming precipitates of albumin and gelatin, which are insoluble in the body fluids, are capable of acting as astringents. Substances of this class have a peculiar action on mucous membranes, causing wrinkling of their surfaces and diminution of secretion; they precipitate not only proteids and gelatin, but also alkaloids and many glucosids.

The action of astringents, irritants and caustics is largely a matter of degree, the caustics acting as astringents when sufficiently diluted, while all astringents produce at least a transient and slight irritation, and when applied in concentrated form to mucous membranes many of those classed as mere astringents are capable of causing considerable irritation, which in the stomach may give rise to vomiting, and in the intestine to diarrhea. Some astringents are essentially mild in their action, while others, being nearly insoluble, can not be brought into intimate contact with the tissues in concentrated form; these can not produce more than a very mild and fleeting irritation, or stimulation, which is followed by lessened permeability of the capillary walls and diminished congestion.

By their irritant action, drugs of this particular class may increase a severe acute inflammation without being able to produce their typical astringent effect, hence they are not nearly so useful in such conditions as in chronic inflammations. The vegetable astringents owe their action mainly to the presence of tannins, substances belonging to an ill-defined group, possessing an astringent action as their best defined property. Other organic acids play only a minor rôle as astringents. The tannins give blue-black or greenish-black reactions with ferric salts; they precipitate proteids, (leather being the product formed with connective tissue), alkaloids, metals and some other substances; they yield pyrocatechin or pyrogallol on destructive distillation. Their therapeutic actions are independent of their chemical peculiarities, and they are severally indicated rather with reference to the presence or absence of extractive matter.

The combination of tannin with pepsine is soluble in the gastric juice, and this and the insoluble albumin tannates are decomposed in the alkaline juice of the intestine, the tannin forming alkaline tannates which possess little or no astringent action. If the free tannins reach the intestine after the administration of extracts of the crude drugs, they act on the mucous membrane, lessening intestinal secretion; this greatly modifies the bacterial development, and therefore the general intestinal conditions. Some of the metallic albuminates are soluble in an excess of proteid, and when in such a case the liberated acid is corrosive, there is a penetrating corrosive action such as that of zinc or mercuric chlorid. With an insoluble precipitate, such as lead albuminate, which forms an impervious coating, and a mildly astringent acid, like acetic, there is a typical astringent and non-irritant effect.

The same astringent substance may be used in a variety of conditions, and a number of different astringents are applicable to a given condition. A better acquaintance with the different tannins may lead to the selection of certain ones for particular cases, but at the present time we are guided more by the physical condition in which a given one is available; thus the official tannic acid is readily dissolved in the stomach, where it combines with the proteid of the content, or of the mucous membrane, whereas the tannin of gambir (gambir replaces the catechin of the Pharmacopœia of 1890) is protected by the presence of gum and extractives, and so passes into the intestine, there to exert its astringent effect. We can not attempt anything like a complete enumeration of the various uses of each of the astringents, but must

content ourselves with summarizing briefly the principal indications of astringents and some of the chief characteristics of the more common remedies of this type.

Uses of Astringents.

Astringents are used internally in the treatment of diarrhea and dysentery, in congestion of the mucous membrane of the stomach and intestines, and for hemorrhage in the alimentary canal and other directly accessible regions. The use of astringents—either organic or inorganic—for their effects on parts which can only be reached by way of the blood vessels is wholly irrational, and when benefit follows it is not due to the astringent action, since by their very nature astringents can not exist free in the blood in sufficient concentration to exert an astringent action. Traces of tannin are not astringent, any more than they are irritant, and astringents act only when brought into intimate contact with the tissue in sufficient concentration.

The metals are poisonous when absorbed, and, as a rule, vegetable astringents are to be preferred for internal administration, particularly when they must be used for a considerable period. Pure tannin, or tannic acid, as it is designated in the Pharmacopœia, may be used locally whenever a purely astringent action is indicated; for example, when secretion is excessive, and when it is desired to harden the skin in order to prevent excessive sweating.

The treatment of accessible, inflamed, mucous membranes with antiseptic solutions, and more particularly with solutions of hydrogen dioxide, has greatly lessened the use of astringents, and the cleansing of an infected surface should be a routine procedure even when an astringent is to be applied subsequently. Dry tannin insullated against an elongated palate often affords instantaneous relief.

Tannin in the pure state is rarely used internally because of its irritant action on the stomach, one of the preparations of astringent drugs being preferred in such cases. The dry powder acts as a styptic when applied to bleeding surfaces, but it must be borne in mind that tannic acid and all other astringents when given by mouth exert their astringent action only on the alimentary canal.

The various proprietary remedies, composed of tannin and albumin, gelatin or aluminum, have not been shown to possess any decided therapeutic advantages over the official astringents, and several of the proprietary compounds, owing to their variable composition, must necessarily be uncertain in their uses and action.

Tannic acid in simple solution combines with the albuminous contents of the stomach, and with the mucous membrane itself if the stomach be empty, and the tannin in concentrated solution; it may then give rise to vomiting and even to diarrhea. This irritant action of the astringents leads to the use of several of them, alum, and zinc and copper sulphate, as emetics.

Tannin, being a precipitant of alkaloids, is useful as an antidote to those poisons when they are in the stomach—not when they have been given hypodermically, except possibly in the case of morphia which is excreted into the stomach. The tannates thus formed are slowly broken up, and the stomach must be evacuated by emetics, or, preferably, by the stomach pump, as promptly as possible, tannin being added to the water which is used to wash the stomach after evacuation. Tea and coffee contain tannin, and, since they are almost universally available in emergencies, their use is very common. Torald Sollmann¹ made some experiments to determine the efficiency of infusions of tea and coffee as precipitants for various alkaloids and metals, and found the infusion of tea much the more active, but neither of them very reliable for the commonly used alkaloids, while the only metals for which tea (infusion) would be useful are mercury, lead and silver. As a single dose of lead never gives rise to poisoning, and as poisoning with silver salts is extremely rare, we must conclude that poisoning with mercuric salts is practically the only instance likely to be encountered in which tea would prove to be an effective precipitant. The use of tea and coffee as stimulants in poisoning depends mainly on the caffeine, and, of course, these remarks as to their limitations do not apply to the stimulant use of them.

¹ Journal of Medical Research, vol. vii, No. 1, p. 43.

VEGETABLE ASTRINGENTS.

ACIDUM TANNICUM.—U. S.—This is a light yellowish amorphous powder of a characteristic odor and a strongly astringent taste; it is very soluble in water, alcohol or glycerin.

Average dose: 0.5 gm. (8 grains).

GLYCERITUM ACIDI TANNICI.—U. S.—A 20 per cent. solution of tannic acid in glycerin.

Average dose: 2 cc. (30 minims).

TROCHISCI ACIDI TANNICI.—U. S.—Each troche contains 0.06 gm. (1 grain) of tannic acid with sugar and tragacanth, flavored with orange-flower water.

These troches are used almost exclusively in affections of the mouth and throat.

Gambir (catechu), kino, krameria and many other vegetable drugs contain large amounts of their peculiar tannins, together with mucilaginous and other extractive matter which tends to prevent the tannin from forming compounds in the stomach and thus preclude its action on the mucous membrane before it comes into the intestine, hence the preparations of these substances are more useful in the treatment of diarrhea than are pure tannin and its preparations.

GAMBIR.—U. S.—Gambir was introduced into the present Pharmacopœia to replace catechu of the earlier editions. It is an extract prepared from the leaves and twigs of *Ouvouparia gambir* and occurs in irregular masses, varying in color from reddish brown to a pale brownish gray. It is odorless, but has a slightly bitter, very astringent taste, with a sweetish after-taste.

Average dose: 1 gm. (15 grains).

TINCTURA GAMBIR COMPOSITA.—U. S.—This represents 5 per cent. of gambir and 2.5 per cent. of Saigon cinnamon in diluted alcohol.

Average dose: 4 c.c. (1 fluidrachm).

TROCHISCI GAMBIR.—U. S.—Each troche contains 0.06 gm. (1 grain) of gambir with sugar and tragacanth, flavored with orange-flower water. These troches are well adapted for use in sore throat, after the throat has been sprayed with a solution of hydrogen dioxide, instead of the astringent gargles which were formerly so much in vogue.

KINO.—U. S.—The inspissated juice of *Pterocarpus marsupium* was introduced into medicine by Dr. John Fothergill about 1757. Like Gambir, it may be given as a powder, preferably combined with opium and aromatics, as in the compound powder of Kino N. F.

Average dose (of kino): 0.5 gm. (8 grains).

TINCTURA KINO.—U. S.—The strength of this preparation has been reduced to 5 per cent. to obviate its tendency to gelatinize.

Average dose: 4 c.c. (1 fluidrachm).

The following prescription, though somewhat complex, is a slightly modified form of one used in certain hospitals with satisfactory results; although the chalk is alkaline, it does not appreciably lessen the astringency of the mixture, as do the carbonates of the alkalis which exist in the intestine. The compound tincture of gambir, or the tincture of krameria, may be used instead of the tincture of kino.

R. Creta preparata.....	3i	4
Tinctura kino.....	5iv	15
Tinctura opii.....	m. v	3
Spiritus chloroformi.....	m. lxxv	5
Aque mentha piperite.....	5x	40
Syrupi aurantii q. s.....	3iii	100

For children of from 3 to 10 years of age, from one-half to one teaspoonful of this mixture may be given every two or three hours; for adults the dose is one tablespoonful.

Another combination of chalk which has attained very great popularity in the treatment of diarrhea is the:

MISTURA CRETE.—U. S.—Chalk Mixture has the following composition:

R. Creta preparata.....	gr. x	6
Pulveris acacie.....	3i	4
Pulveris sacchari.....	gr. cl	10
Aque cinamomi.....	5x	40
Aque q. s. ad.....	3iii	100

Average dose: 15 c.c. (4 fluidrachms).

The mixture is so well known that it is mentioned merely as a reminder of one of our best and simplest remedies for diar-

rhea. It is peculiarly adapted for combating the diarrhea of children. Severe cases may require the addition of a few drops of the deodorized tincture of opium to each adult dose, or a corresponding addition of paregoric (the camphorated tincture of opium) for children.

The vegetable drugs that contain tannin are so numerous, and their general therapeutic actions are so similar, that we shall merely enumerate the following well-known vegetable astringents and the available, official, preparations:

Rubus (blackberry-root bark)—fluidextract and syrup.

Rose—fluidextract and syrup.

Geranium—fluidextract.

Hematoxylon—extract.

Rhus Glabra—fluidextract.

Gallic acid is sometimes recommended as an astringent, but it possesses no such action except that of any very weak acid, and it is absolutely useless for hemorrhage in the lungs, kidneys and other regions reached only by the circulation.

Though opium does not contain tannin, it would be a distinct omission if we failed to mention some of its indications in this place, since these articles are intended primarily to call attention to the possible therapeutic uses of the official substances, and since the arrangement into groups, such as astringents, is merely for convenience. Small doses of any of the opium preparations afford one of the surest means of relief in diarrhea. They are commonly combined with astringents, inorganic as well as organic, with excellent results, despite the chemical incompatibility existing between the alkaloids and the various tannins or metallic salts. The preparations of opium have been mentioned in the earlier chapters, and we now merely wish to call attention to methods of combining these agents.

R. Tinctura gambir composita.....	3i	30
Tinctura opii deodorata.....	m. x	5
Bismuthi subnitrat.....	3iiss	10
Aque camphore q. s.....	3iii	100

Sig.: One teaspoonful hourly for three or four hours, then every two, three or four hours.

Any one of the insoluble bismuth salts may be used, and tincture of kino or krameria substituted for the compound tincture of gambir. Similarly, an appropriate amount of the camphorated tincture of opium may be substituted for the deodorized tincture. When it is desired to give the same active ingredients in the form of a dry powder, the following may be used:

R. Opii pulveris.....	gr. v	3
Bismuthi subnitrat.....	gr. cl	10

M. Ft. pulvis et div in Chart x.

Sig.: One powder to be given every two, three or four hours, according to the needs of the patient.

Here, again, the combination may be almost endlessly varied by using one of the other forms of insoluble bismuth salts, the deodorized opium, or by adding a small proportion of one of the vegetable astringents like kino or gambir.

The pill of lead and opium is well adapted for securing a very slowly soluble form for administering these drugs. The pill is useful in diarrhea, but must not be long continued, lest it give rise to lead poisoning.

R. Plumbi acetatis.....	gr. ii	1
Opii pulveris.....	gr. i	105

To be made into one pill.

Sig.: One pill to be given three or four times a day.

Inflammation of the stomach and intestine and also gastric ulcer may be treated by an insoluble astringent powder which not only relieves congestion by its astringent property, but also forms an insoluble protective covering, preventing the contact of irritating particles of food and the gastric and intestinal secretions, besides lessening the amount of these secretions.

(To be continued.)

Altruism in the Medical Profession.—Winfield S. Hall, Chicago, in the *Bulletin of the American Academy of Medicine*, says: Every profession, every occupation in life, affords its opportunities for altruism, but he who chooses the medical profession must do so with the knowledge that to be a useful and successful member of that profession he must subordinate self to the welfare of his fellow-men.

Clinical Notes

QUININ IN PNEUMONIA.*

A. L. GUSTETTER, M.D.

Acting Assistant-Surgeon, U. S. Public Health and Marine Hospital Service.

NOGALES, ARIZ.

Following the cases of pneumonia reported in Dr. Galbraith's article in *THE JOURNAL* Feb. 10, 1906, I have had many other cases, in all of which I have treated the patients according to Dr. Galbraith's method, but with a very much better result.

Pneumonia is a very prevalent disease in Nogales and vicinity. My mortality in pneumonia cases was formerly nearly 80 per cent. So fatal had the disease become that all persons possessing enough of this world's goods to carry them to the sea level refused to remain here after becoming aware of the nature of their affliction. The results reported in the following cases, I am pleased to state, are the rule and not the exception. Thus far I have not had a death from pneumonia since I began the quinin treatment according to Dr. Galbraith's method.

CASE 1.—A male, aged 24, helper on railroad.

History.—On January 31 he was suddenly seized with severe pain on the right side of chest, violent and painful coughing and inability to take a full breath without seriously increasing the pain over the right chest.

Examination.—I saw him for the first time February 1, when I encountered the following conditions: At 3:30 p. m. his temperature was 102.6, pulse 100, respirations 32. Breath sounds over the upper lobe of the right lung were greatly exaggerated; over the middle and lower lobes they were very faintly heard; on deep inspiration broncho-vesicular breathing was heard.

Diagnosis.—Lobar pneumonia, involving the middle and lower lobes.

Treatment.—I gave 50 grains of quinin and one hour later (4:30 p. m.) I gave him 25 grains more. I then ordered 15 drops of the tincture of iron chlorid to be given every three hours, beginning at 5 p. m. At 6 p. m. his temperature was 102.8, pulse 108, respirations 30. At 7:45 p. m. his temperature was 100.6, pulse 112, respirations 26.

Course of Disease.—February 2, at 7:45 a. m., his temperature was 98.6, pulse 80, respirations 24. He made no complaints of ringing in the ears and felt well enough to sit up in bed. The pain in side had entirely disappeared. Expectoration during the night was blood-tinged. When I visited him in the evening his temperature, pulse and respirations were normal. As no symptoms remained the patient was discharged.

CASE 2.—F. H., male, aged 14, schoolboy.

History.—On February 4 the patient was taken with a severe chill, pain in the right side, coughing and distressed breathing. I was called to see him the following morning.

Examination.—At 9 a. m. his temperature was 103.4, pulse 120, respirations 32. I suspected pneumonia, but the physical signs were not positive. At 4:20 p. m. his temperature was 104, pulse 140, respirations 36. Breath sounds over lower and middle lobes of right lung were suppressed; subcrepitant râles were present.

Diagnosis.—Lobar pneumonia, involving the middle and lower lobes of right lung.

Treatment.—At this time (4:20 p. m.) I gave him 50 grains of quinin, followed by 25 grains one hour later. The nurse was then instructed to give him 15 drops of the tincture of iron chlorid every two hours.

Course of Disease.—At 7:55 p. m. his temperature was 101.4, pulse 132, respirations 40. At 9:15 p. m. his temperature was 103.6, pulse 136, respirations 38.

February 6, at 9 a. m., his temperature was 101.4, pulse 126, respirations 30. Tubular breathing was heard over anterior and posterior surfaces of lower and middle lobes of right lung, and

percussion elicited dullness of consolidation over the same area. He expectorated great quantities of bloody mucus. Pain in the right side had disappeared. I ordered 20 grains of quinin to be given at 10 a. m. and at 12 noon, to be followed by 12 grains every two hours. The iron was continued every three hours. At 12 a. m. his temperature was 101.8, pulse 120, respirations 28; at 6 p. m. his temperature was 102, pulse 114, respirations 28; at 8 p. m. his temperature was 101.2, pulse 110.

February 7, at 8:40 a. m., his temperature was 103.2, pulse 106, respirations 30. I gave him two pills of quinin, containing 20 grains each, at 9:30 and 11:30 a. m. He was then given one pill every two hours until he had taken six pills, or 120 grains of quinin, during the entire day. The quinin was given in pill form because of the nausea that was produced when he took it in solution. My experience with this and with another patient has decided me never to use quinin in any other manner than in solution. The pulse being of good quality, the 15 drops of iron were given every three hours. At 2:30 p. m. the boy's temperature was 103, pulse 108, respirations 30; at 6:30 p. m. his temperature was 101.6, pulse 104, respirations 28.

February 8, at 9:30 a. m., his temperature was 102.4, pulse 104, respirations 26. He felt very comfortable. Expectoration was bloody and physical signs of pneumonic consolidation were well marked on auscultation and percussion. Twelve grains of quinin were ordered given every two hours. At 12 noon his temperature was 102.2, pulse 102, respirations 28; at 5 p. m. the temperature was 101.2, pulse 86.

February 9, at 8:30 a. m., temperature was 101.2, pulse 84, respirations 25. The patient complained of deafness and said that he was blind. He was able to distinguish between light and darkness, but could not distinguish objects. I therefore stopped the quinin during the entire day. The iron was given as usual. At 2 p. m. the temperature was 102, pulse 84; at 5 p. m. the temperature was 102.6, pulse 80, respirations 28. The boy's sight was somewhat better. At 8 p. m. the temperature was 102.6, pulse 82, respirations 28.

February 10, at 9 a. m., the temperature was 103.6, pulse 92, respirations 24. The vision being normal, I gave him 50 grains of quinin at one dose and ordered 12 grains to be given every three hours. At 12 noon the temperature was 102.2, pulse 86, respirations 28. The iron was continued every three hours. At 5:30 p. m. the temperature was 101.6, pulse 84, respirations 20; at 8:30 p. m. the temperature was 102.6, pulse 90, respirations 20.

February 11, at 8:40 a. m., the temperature was 102.4, pulse 86, respirations 22; at 12:20 p. m. the temperature was 102, pulse 86, respirations 22. The boy felt very well; he had no deafness nor disturbance of sight. The administration of 12 grains of quinin was continued every three hours. At 5:30 p. m. the temperature was 100.2, pulse 82, respirations 24.

February 12 (sixth day after the first dose of quinin). At 9:30 a. m. the temperature was 98.4, pulse 72, respirations 20. The patient had slept well during the night. He had neither cough nor expectoration. Fifteen drops of iron were administered every four hours. At 6 p. m. the temperature was 99.2, pulse 74, respirations 20.

February 13, temperature was 97.4, pulse 78, and the patient was discharged.

Remarks.—Out of about thirty cases of pneumonia treated according to Dr. Galbraith's method this was the first case showing any symptoms of quinin poisoning, i. e., the profound deafness and the almost complete blindness. Fortunately, both of these symptoms passed off within ten or twelve hours, and now the boy can see as well as ever.

CASE 3.—Mexican girl, aged 13.

History.—On February 15 the patient had a chill lasting about twenty minutes and later began to feel feverish. At the same time she felt a severe and sharp pain in her right side. Nothing was done for her and I was summoned the next morning, when I found the following conditions:

Examination.—Temperature was 104, pulse 150, respirations 34. The pulse was very weak and almost imperceptible. On auscultation, subcrepitant râles were heard over the lower lobe of the right lung. Breathing was very labored. The patient preferred lying on the affected side and suffered great pain when she was turned on the left side.

* See Editorial on page 504.

Treatment.—I diagnosed this as a case of lobar pneumonia and gave the girl 50 grains of quinin and ordered 25 grains more to be given one hour later, making 75 grains of quinin in one hour. Ten drops of the tincture of iron chlorid were administered every two hours.

Course of the Disease.—At 6 p. m. the temperature was 98.6, pulse 96, respirations 24. The pulse was of very good quality. The pain had left her and the cough was less frequent. This patient never suffered from deafness.

February 17, at 9 a. m., the temperature was 98, pulse 84, respirations 20. The patient was free from cough and pain and was allowed to sit up in bed.

Remarks.—In reporting a case with so prompt and effective a cure, I know that many will think there must have been a mistake in the diagnosis, but I felt just as certain that I was dealing with a genuine case of pneumonia as though I had seen the case go through the whole train of symptoms.

CASE 4.—Mrs. C., aged 23.

History.—February 2, at 2 a. m., I was called to deliver a retained placenta, the woman having one hour previously given birth to a child that had been dead at least a month. I delivered the placenta without any difficulty and, the family having engaged the services of a midwife, I left after instructing them to call me in the event of fever or any other symptom arising.

February 3, at 9 p. m., I was called to see the patient, as she was suffering from a chill and cough. Her temperature was 102, pulse 140. The lochia was very scant, but of purely normal odor. I ordered a capsule containing acetanilid 3 gr. and citrated caffeine $\frac{1}{2}$ gr. to be given every two hours.

February 4, at 9 a. m., her temperature was 102, pulse 150, respirations 26. Cough was more persistent. She complained of severe pain over right lung. Her breasts, which had been tightly bandaged, were also painful. At 5 p. m. her temperature was 104, pulse 150, respirations 30. The pain on the right side was much worse and breathing was labored. Auscultation breath sounds were very harsh. Having satisfied myself by examining the vagina and uterus that there was no possibility of any infectious or poisonous process going on in the uterus, I decided to wait a few hours before giving her the quinin treatment. At 9 p. m. her temperature was 104.8, pulse 165, respirations 36. On listening to the lower lobe of her right lung I now heard the sub-crepitant râles very plainly, and the breath sounds over the rest of the lung were greatly exaggerated. The patient had great difficulty in breathing. I decided that it was a case of lobar pneumonia and not puerperal septicemia.

Treatment.—I gave her 50 grains of quinin and followed this in one hour with 25 grains more. Fifteen drops of tincture of iron chlorid were given every two hours.

Course of Disease.—On February 5 the temperature was 98.6, pulse 80, respirations 20. Pain had entirely disappeared. Several times during the night the patient expectorated bloody sputum; cough was not frequent. At 5 p. m. the temperature, pulse and respirations were normal. The patient felt fine, but remained in bed to complete the ten days following confinement.

Remarks.—This case was of great interest to me from the standpoint of differential diagnosis. Under the circumstances the promptness with which the symptoms were relieved was certainly gratifying to me.

QUININ IN PNEUMONIA.*

A. S. V. MANSELD, M.D.
ASHLAND, NEB.

Under the caption, "Quinin in Pneumonia," in THE JOURNAL, March 3, Dr. J. B. Cutter complains that Dr. W. J. Galbraith claims originality in the use of large doses of quinin, when Dr. A. J. Giessy pursued that course in 1894.

Permit me to direct attention to page 165, vol. v, Ziemsen's "Cyclopedia of the Practice of Medicine," published in 1875, a translation of Prof. Theodore Juergensen's classic article on "Croupous Pneumonia," the disease under consideration. There he says:

"When the fever is intense, 77 grains may be given to a strong adult and 15 grains to a child under 1 year, always in one dose. I have repeatedly used both of these amounts. I have acquired my experience by gradually increasing doses, and I have never seen any harm done; in fact, it is my firm belief that even these are not the extreme limits as to quantities."

Personally, I have used just this treatment for thirty years within my limited opportunities—and so much for priority. Dr. Galbraith, an old acquaintance of mine, certainly deserves great credit for bringing into prominence this old treatment of Juergensen's, which he uses exactly as I did, namely: with perfectly normal *prima vie*, for the reduction of high temperatures and the resulting tone to the weakened heart muscle caused by the former. Incidentally, both used it, the former without and the latter (Galbraith) with a full knowledge of bacterial poisoning removed by the large doses of quinin. Nothing new under the sun, is there?

In this connection it may not be out of place to say that Dr. Galbraith's publication demonstrates that nihilism in the use of individual drugs simply means lack of knowledge of their proper uses, with the consequent reliance on proprietary mixtures, which only too often are void of substance and, consequently, of action. Again, is it not a pity that such masterly treatises as Ziemsen's Cyclopedia seem almost forgotten by the physician of to-day? What a wealth of experience he misses!

AN UNUSUAL CASE OF SPONTANEOUS DISLOCATION OF THE SHOULDER.*

JULIUS H. COMROE, A.M., M.D.
YORK, PA.

Patient.—Chas. M., white, aged 16, schoolboy.

Family History.—Entirely negative.

Previous History.—Other than the ordinary diseases of childhood, the patient has never suffered any serious illness. No history of traumatism can be elicited.

Present History.—Since early childhood the patient has at all times been able, by means of a certain series of manipulations, which consisted, for the most part, in raising and externally rotating the shoulder. "To throw both joints out of their sockets," producing, as a careful examination revealed, a complete sub-coracoid dislocation. He had also learned easily to replace the bones by a reverse movement, and in neither case was there any pain produced. At times, while engaged in active gymnastic exercises, e.g., club swinging, basketball, etc., the luxation was voluntarily produced.

During the past three months, however, he began to suffer some inconvenience when the left shoulder was either voluntarily or involuntarily dislocated, and at the same time he noticed that there was some difficulty in replacing the bone on that side. This "inconvenience" gradually grew into a dull pain, which at times was quite aggravating, and the difficulty in reposition became proportionately more marked. For these reasons he was referred to me for diagnosis and treatment.

Physical Examination.—The boy was well nourished, of good athletic physique. The appearance of the shoulders is characteristic. They are broad and extremely flat, due largely to the underdeveloped deltoids and the resulting prominence of the acromion processes (Fig. 1). The humeri are rather preternaturally movable, abduction bringing the arms to an almost parallel vertical position. Neither bone nor joint crepitus could be elicited. By the manipulations above detailed there is at once produced all the characteristic objective signs of sub-coracoid dislocation of both shoulders, with the exception of abduction of the arms (which is present in slight degree); the outer aspects of the deltoids are flattened; the acromion processes are very prominent (Fig. 2); the normal position of the tuberosities below the latter are now occupied by hollow spaces, into which the tips of the fingers can be easily slipped; the humeral heads can easily be palpated in the axilla, and in forced extension can even be seen.

I made a very careful fluoroscopic examination, which was

* See Editorial on page 804.

* Read before the York County (Pa.) Medical Society.

also seen by Dr. W. F. Bacon, chief surgeon of the York Hospital, and by Dr. L. M. Hartman. In the normal state there appeared to be no gross anatomic malformations in the bony structures of the joint, with the possible exception that the glenoid cavities were more shallow than those of several others which the author examined for comparison. The capsular ligaments, however, could be very distinctly outlined with a medium tube, and the left one was unmistakably larger than its fellow on the opposite side. The latter produced a homogeneous picture, whereas the former (the left) appeared much darker centrally, as though an obstructive fluid was present, probably an inflammatory exudate from the synovial membrane. This would easily account for the subjective symptoms on the left side (subacromioclavicular synovitis, with exudate) and their absence on the other. The bones were voluntarily dislocated before the fluoroscope, and their course was seen to be downward, forward and upward, the head reposing immediately below the coracoid process, with the lesser tuberosity being anterior, showing, therefore, that external rotation had taken place. In this new state it appeared that the head of the bone was lying in an abnormally large pouch, as it were, which was the chronically enlarged capsular ligament. The bones were replaced in the exact reverse order.

Figure 1.

Treatment.—I advised encasing the left shoulder in a Velpeau fixation dressing and continuing treatment as in an acute traumatic luxation. This was advocated for the double purpose of "fixing" the joint and at the same time of producing absolute rest for the inflamed surfaces. For the right shoulder I advised massage, passive motion, and regulated, gentle gymnastics, to improve the muscular and ligamentary tone. I also recommended that in about six or eight weeks the proceeding that proved most beneficial should be further practiced on both sides.

I could find no other similar case of double dislocation, purely spontaneous, in medical or surgical literature.

According to DaCosta, spontaneous (pathologic or consecutive) luxations are usually present in a joint which has been disabled by some preceding or existing form of disease, e. g., chronic synovitis, tuberculous disease, rheumatoid arthritis, and at times in severe typhoid infections. In other words, it is neither traumatic nor congenital. When the *Typhoid bacillus* is responsible for the infection, the hip is the joint most frequently attacked (with luxation), and the most frequent type it

assumes is posteriorly on the dorsum of the ilium. The latter form is at times not recognizable until convalescence, and its reduction is often very obstinate. In Charcot's disease, spontaneous dislocations are rather common, the joints most frequently attacked being the knee and the hip, in the order named. In this latter pathologic condition, there is a more or less rapid destruction of all the joint constituents, with softening and marked relaxation of all the ligaments, thus permitting a greater range of motion and favoring dislocation.

The treatment in these pathologic luxations, when resolution does not set in, consists in the application of suitable apparatus or in resection as a final resort. I am of the opinion that these pathologic luxations should not be referred to as "spontaneous," and that the latter term should be restricted to those cases in which no congenital, traumatic or pathologic etiologic factor can be ascertained.

Figure 2.

HUMERUS.

Unilateral spontaneous luxations of the shoulder are not infrequent, due to the very shallow glenoid cavity and to the great mobility and exposure of the joint constituents. They are invariably anteriorly dislocated, since there are no powerful muscles to impede the course in this direction. The subcoracoid variety is the most frequent, as, to become a subglenoid dislocation, the powerful triceps tendon must be ruptured, and this is rarely accomplished, unless as a result of violent traumatism. In these cases of spontaneous dislocation of the shoulder there must be a movement of extreme abduction, which causes the acromion process to strike on the neck of the humerus, and thus to tilt the bone out of its socket, the acromion process acting as a fulcrum, the distal portion of the arm as a long lever, and the portion of the humerus between the tuberosities and the head as a short lever. It is, therefore, a disturbance of leverage, essentially, that produces a spontaneous dislocation.

SYMPTOMS.

The characteristic appearance of the patient, so well described in all text-books, is, in a large number of cases, pathognomonic of the condition. In addition, the head of the humerus is readily felt in the axilla, and when the arm is actively raised up it may even be seen as a globular prominence; the prominence of the shoulder is no longer the greater tuberosity of the bone, but rather the acromion process, since the head is pushed under the coracoid process, causing the absence of the characteristic roundness and the substitution of the "flattened" shoulder; the deltoid is naturally stretched down from the acromion to the middle of the shaft of the humerus externally, and this tends to throw the elbow out from the body. The elbow can not be brought to touch the body (Dugas' sign), since the head is wedged in between the acromion and coracoid processes.

TREATMENT.

If spontaneous reposition can not be accomplished, Kocher's method will prove successful in most cases. If not, one of the many modifications variously described will invariably suffice. In rare instances, however, this is found to be impossible, when excising or wiring (Beck) must be resorted to. At the same time the hygienic condition of the patient should be carefully regulated and the general health improved so as to reinforce the weakened joint. Two patients with persistent spontaneous unilateral dislocations of the shoulder were operated on by Ricard with success. His method is to expose the front of the joint by an incision between the deltoid and pectoralis major, and a second incision from the upper end of the first outward along the margin of the acromion. The inner portion of the capsule is now pinched into a transverse fold, and several vertical sutures placed so as to include the tendon of the subscapularis below and the thick capsule above.

A CASE OF DOUBLE UTERUS.

C. H. NEWTH, M.D.
PHILOMATH, ORE.

I wish to report a case of double uterus. I first saw the patient one year ago, when called to determine whether she was pregnant or not. She had been married five years without becoming pregnant, but had not menstruated for five months and now thought she felt motion. She called me in because the tumor seemed to be all on the left side.

On making a vaginal examination, I found the vagina divided by a septum, and at the upper end of each side of the vagina a cervix and uterine cavity. As the patient was certainly pregnant, I could not use a sound. She was pregnant on the left side. The finger passed naturally up the right side and was with difficulty passed on the left side. I asked her if she knew that she was different from other women and she said no, but on further questioning I found that both she and her husband knew of the condition, but did not know that it was different from other women. She miscarried one month later and sent for me, but, as I was away from home, she had no physician.

She miscarried again, at nearly four months, two weeks ago. I was called in four days afterward and found a retained and putrid placenta. She thought she had passed something from the right side two weeks previously, and stated that the fetus came from the left side. I removed the placenta and she is entirely recovered.

On examination I found that I could introduce one finger in each cervix at the same time. I examined the inside of the left uterus, digitally, and am convinced that there is no connection between the two cavities. There is now a rupture of the septum close to the uterus large enough to admit the tip of my finger, so that I could pass the finger up the right side of the vagina and feel the left os as well as the right. I think there is no doubt, from the conditions, that intercourse always took place on the right side, but that the right side is rudimentary, or infantile, and that conception could not take place on that side, and that it was very unlikely that the semen entered the left side.

At the first examination I found it difficult to introduce the finger into the left half of the vagina on account of the small opening, and I am reasonably certain that the male organ had never penetrated that side, although the left half of the vagina was roomy enough when once entered. At the second examination, I found the same condition, except that the opening was larger and that there was also a laceration of the upper portion of the septum. At this time the finger, passed straight in, would always enter the right side of the vagina, and my theory is that the right half of the uterus is rudimentary and that only after five years of married life the semen was accidentally introduced into the left half. The septum was probably torn when the miscarriage occurred, thus accounting for the second impregnation. I think the probability is that she will never carry a fetus to term, on account of the right side of the uterus not dilating or entering into the physiologic growth of the gravid uterus. This case corroborates the statement generally made that abortion frequently occurs in cases of uterus didelphys.

AN ISOLATED CASE OF FRIEDREICH'S ATAXIA.*

ARTHUR H. DODGE, M.D.
PHILADELPHIA.

The following case of Friedrich's ataxia presents nearly all the symptoms of the disease, according to the synopsis of Soca and Ladame, except the familial feature. Although this familial tendency is usual, cases in which direct inheritance can be traced are rarely observed. The cases of Gowers, Osler and Carre are instances. Isolated cases are far from rare and have been reported, showing nothing more of note than the sporadic occurrence.

Patient.—J. M., aged 24, single, white, male.

Family History.—Mother is living, aged 60. Father died as the result of an accident at the age of 55. Parents were not related, and no nervous disease of any nature is known in the family. The father was an alcoholic. Alcoholism in parents has been spoken of as an important etiologic factor; Friedrich in his first cases insisted on the causal relationship of alcoholism in parents to this disease. The case of Vizioli was unique in this particular. Our patient was the youngest of six children. Three brothers died in childhood, two the result of measles and one from a severe burn. A brother of thirty years and a sister of twenty-seven are living in good health and show no signs of a similar affection; and they are likely to be free from this disease according to the observation of Soca that the onset of the disease commences at the same age in members of the same family.

History.—The patient was admitted to the nervous wards of the Philadelphia Hospital, in Dr. Lloyd's service, May 13, 1905, stating that the onset of his trouble was noticed after an

* From the service of Dr. James Hendrie Lloyd in the Philadelphia Hospital.

attack of influenza at the age of seventeen. The first symptom was unsteadiness and uncertainty in walking. The gait progressively became worse, and his friends noted its resemblance to a drunken man's gait. The patient frequently had to take hold of surrounding objects to prevent falling. Unsteadiness of much less extent was noticed in the upper extremities at about the same time. Three years after the onset of the disease the patient ceased walking. At no time has the patient had any pain, and the function of the rectum and bladder has been normal, except on one or two occasions when he has noticed a delay in starting his urine. The patient denies all illnesses except the milder diseases of childhood; and evidence of syphilis is wanting. He admits a free use of alcohol after the onset of his disease.

Examination.—The patient is confined to a chair, but needs no help from anyone to get to and from his bed nor does he require help in dressing. The facial movements are well performed. The hair is plentiful, black in color but profusely streaked with grey hairs. The pupils are equal and react promptly in convergence. Direct and consensual light reflexes are prompt. The visual fields are not contracted, and the ocular movements are normal. There is nystagmus of prominence on lateral deviation of the eyes. Examination by Dr. Hansell, May 19, 1905, showed the eye grounds to be normal. There is nearly constant oscillation of the head, resembling the motions used to signify yes and no. This motion is increased in frequency and amplitude when the patient is watched; also while he is talking. Speech is slow, hesitating, jerky, thick and slightly slurred, but not truly scanning. The mentality of the patient is good and there seems to be no change according to the statement of his brother. The heart and lungs show nothing abnormal. The urine contains no abnormal constituents. Strength in the extremities is well preserved. The grip in the right hand is 42 and in the left 39 on the scale of the dynamometer. There is no atrophy. The limbs are not spastic. Muscle sense is intact. Sensation over the entire body is normal. No pains of any character. Bladder, rectal and sexual functions about normal. Ataxia is present in the hands and arms to a considerable degree, but the ataxia in the lower extremities is more marked. The patient walks with support, and in doing so places the feet widely apart, and the legs are thrown about in a helpless manner. While the patient is standing the head and trunk sway very much and the patient presents the attitude of a man very drunk. The closure of the eyes causes no increase in the swaying, but it is difficult to say whether the swaying could be increased. There is antero-posterior curvature of the spine in the cervico-dorsal region, but no scoliosis. The feet are shortened from before backward, and the arch is greatly increased. The toes are dorsally flexed, especially the great toe, and the extensor tendon of the great toe is prominent. There is not the flexion of the distal phalanx which is usual.

The knee jerks and Achilles jerks are absent. The biceps and triceps jerks are present and about normal on either side. The cremasteric and epigastric reflexes are present. The presence of the Babinski reflex in Friedrich's disease is not usually spoken of with any degree of clearness in either the text-books or reported cases. In this case the Babinski reflex is very prompt and active on either side. In some of the text-books the Babinski reflex is spoken of as constantly present in this affection. In two other cases now in the Philadelphia Hospital, in a brother and sister, the Babinski reflex is absent; but these cases have advanced into the paralytic stage of the disease.

Course.—Nov. 1, 1905.—The course of the disease has been progressively downward. The speech defect and the nystagmus are more pronounced. The ataxia is greater, especially more marked in the arms since admission, and the arm reflexes are lessened. The general health is not so good as on admission.

DISCUSSION BY DR. LLOYD.

The differential diagnosis of Friedrich's ataxia offers no special difficulty, unless it be with reference to multiple sclerosis. But in Friedrich's ataxia the onset of the disease with ataxia in the lower limbs, the abolition of the deep reflexes, especially the knee-jerks, the ab-

sence of spasticity in the muscles, the absence of optic atrophy (occasionally seen in multiple sclerosis), are all significant of Friedrich's disease. The so-called cerebellar hereditary ataxia of disease, in which there are increased tendon reflexes, paralysis of ocular muscles, with disorder of sight, is not thus far a distinctly differentiated disease and is so rare as hardly to lead to a confusion with the true Friedrich's ataxia. There is a type, however, of hereditary, or at least congenital, ataxia paraplegia which deserves mention. In this disorder there is ataxia with some spasticity and actively increased knee-jerks; also disorder of speech, such as stammering, jerky enunciation, with or without nystagmus, etc. This is sometimes found in children who have suffered injury at about the time of birth, and is thus in no sense either a familial or a hereditary affection.

New Instrument

A NEW OPERATING TABLE.

REVISED AND IMPROVED.

J. F. BALDWIN, M.D.
COLUMBUS, OHIO.

About five years ago a description appeared in *THE JOURNAL* of a new operating table which I had devised after several years of study. Daily use of the table demonstrated, however, the existence of two or three weak points, which have finally been eliminated, and several new features have been added, and now the table seems to be about perfect.

The main points of the table, as first presented, and which are retained, are: 1. Simplicity of construction. 2. The field of operation not changing when the patient is put in the Trendelenburg position. 3. The position of the patient quickly

and easily changed by the anesthetist. 4. The patient maintained in the Trendelenburg position by shoulder straps, or (as I prefer) by tying the legs to the leg piece.

The recent improvements add the following points: 5. The leg extension-piece automatically drops to the proper angle when the patient is placed in the Trendelenburg position. 6. The bridge, by which the patient is arched forward as desired in kidney, gall-bladder or stomachic work, maintains its position without catch of any kind and can be raised or lowered from either side. 7. The copper hot-water reservoir (electrically heated, if preferred), to keep the top of the table warm if desired for protracted operations on feeble patients.

The illustration shows the usual glass top, but I much prefer metal.

SATURDAY, MARCH 17, 1906.

QUININ IN PNEUMONIA.

In the high and dry regions of Mexico and the southwestern part of our own country, pneumonia has long been dreaded by physicians because of its frightful mortality. It is to be hoped that the reports concerning the treatment of this disease by large doses of quinin, as advocated by Galbraith¹, may continue to be encouraging. We have no desire to throw cold water on this method of treatment. We shall gladly open our pages to careful reports along this line, and trust that the good reports from the southwest may be substantiated by experience in other parts of the country. Yet we wish to call attention to two or three facts that should be borne in mind.

In the first place, the use of large doses of quinin in pneumonia is not new. It has been given a thorough trial. It has not proved a specific in other hands. As Dr. Mansfeldt² says in his communication, Juergensen thirty years ago advocated its use in large doses (33 grains) giving this amount in one dose as an antipyretic—and often repeating this dose in 48 hours—but seeing also an improvement in the condition of the pulse, respiration and nervous state of the patient. Juergensen, however, made no claim that quinin was a specific, and his death rate was between 10 and 20 per cent.

Again, this same clinician uttered some truths concerning pneumonia that will bear repetition to-day. We quote from the same article in Ziemssen's *Cyclopedia*: "When we realize that we have to combat not an 'inflammation' but rather a constitutional disease, and one, moreover, of comparatively short duration, we readily fall into an expectant treatment which bides its time, interferes only when necessity requires, and does not see in the mere name of the disease an indication for attack." And in another place he says it is right to "do almost nothing for, say, 80 per cent. of the cases, and to employ the most active treatment for the other 20 per cent." The lessons of the self-limitation of acute infectious diseases is a hard one to learn. It is difficult to realize that from 60 to 80 per cent. of pneumonia patients will recover if let alone, and in selected cases where the extremes of life are excluded, as well as individuals who

are weakened by previous disease, the mortality is low. Petresco's³ results—a mortality of about 2 per cent.—from the use of enormous doses of digitalis, illustrate this, his patients being young soldiers in whom previously existing disease of heart, kidney, etc., had been excluded by rigid physical examination at the time of admission to the army. In private practice it is no uncommon thing for a busy physician to treat 40 to 50 consecutive cases of pneumonia by the so-called expectant or symptomatic plan, and to have no deaths. And another phenomenon of not infrequent occurrence is an apparent abortion of a pneumonia or an early crisis. Crisis on the third day of pneumonia while not common is by no means a remarkable rarity. These facts carefully considered should make one hesitate about ascribing the recovery or even the early recovery to the particular drug that has been given.

Before conclusions are drawn there should be no weak points in the diagnosis. Pleurisy, bronchopneumonia, bronchitis, influenza, malaria, etc., should all be carefully ruled out. Some of the cases reported are not, to judge from the records, conclusively pneumonia. To cite an example, Case 4, in the report by Dr. Gunstetter in this issue, might well be pulmonary embolus following parturition. And in not a few other reported cases the diagnosis is not always above criticism.

While, therefore, we welcome any careful clinical observation that will help to a better understanding of the treatment of the all too prevalent and fatal pneumonia, we would call attention to the fact that the treatment by quinin is old and has once been discarded; that results to be convincing must be based on the observation of a considerable number of cases in which the diagnosis is indisputably correct; and that the fact must not be overlooked that the great majority of patients under the age of 50 or 60 will recover under any plan of treatment if it be not harmful.

BEDBUGS AND DISEASE POSSIBILITIES.

Though the bedbug has been known as an extremely unmanageable pest of humanity almost as long as history runs, very little has been ascertained with scientific definiteness regarding its habits and life history until recent years. Somehow the very thought of the insect and certain objectionable features that it is known to possess, such as its defensive as well as offensive odor, have deterred students from taking up the investigation of its life cycle, though its anatomy was very thoroughly studied over twenty-five years ago by Landois and others. In recent years the possibilities of the conveyance of diseases of various kinds by means of this insect parasite have been recognized and renewed interest has been aroused in everything that concerns it. For example, in smallpox epidemics, the spread of the disease through cheap lodging houses is more fre-

1. Galbraith: *THE JOURNAL A. M. A.*, Jan. 28, 1905, and Feb. 10, 1906. See also reports by Gunstetter in this issue, p. 799, and by Cutter, March 3, 1906, p. 671.

2. *THE JOURNAL A. M. A.*, March 17, 1906, p. 800.

4. Proceedings of XI International Congress in Rome.

quent than through any other means, and the houses in which bedbugs are found seem to furnish a steady supply of victims. This impression was renewed during the recent epidemic of smallpox throughout the United States and Canada. On at least one occasion tubercle bacilli have been found in the blood of the bedbug, and, as in this case a brother of the patient, who had occupied the same bed, had died from tuberculosis, and another brother suffered from a severe and rapidly running form of the same disease, there was more than a suspicion that this parasite was a distributing agent for the disease. There is a definite tradition in Russia frequently repeated by Professor Metchnikoff, in his lectures at the Pasteur Institute, that the bedbug forms an intermediate host or is at least an agent for conveying intermittent fever, so common in certain districts of that country. Its possibilities in the rôle of intermediary in cerebrospinal meningitis are still the subject of investigation.

In these circumstances all possible information with regard to the pest is interesting, and consequently a leaflet issued by the Department of Agriculture should attract attention. This pamphlet is written by Dr. Girault, who has carefully followed the life history of *cimex* or *clinocoris*, as the insect is variously called in scientific nomenclature, and has found important new material with regard to its feeding habits. The adult insect feeds about once in from thirty-six to forty-eight hours, taking nearly fifteen minutes to get its fill of blood. At earlier ages the feeding period is much shorter. Except in susceptible human beings who have a decided idiosyncrasy, no local effect at all is produced by the feeding process. Some individuals, however, suffer from almost intolerable itching and have a series of urticaria-like lesions. The parasite is so prevalent in certain parts of the country, however, that it is evident that those with an idiosyncrasy are comparatively rare. The insect may live from five to ten weeks or even longer without any food. This is especially true during the winter, when, if they have no food, they go into a sort of comatose condition. While each insect seems to live not longer than about 100 days at the outside, some have been known to exist as long as eight months; and it is these that enable the species to continue its existence even under unfavorable circumstances, so that they live from season to season in lumber camps, summer residences, empty apartments and the like.

Another interesting phase of investigation with regard to the bedbug and its connection with disease was carried on by Drs. Girault and Strauss as to whether or not the insect had other host relations besides those with the human race. As is easily understood, the host relations of this insect are greatly increased in importance because of their scope in the potential transmission of disease if they attack other animals than man. It has been found experimentally that at least mice, both living and dead, are attacked by bedbugs and that young mice particularly seem to provide an excellent

supply of food for them. This observation has been confirmed by observations made by Drs. Girault and Strauss, and, as it seems not unlikely that other small animals, including even rats, may also be hosts, the spread of such affections as pest, mouse septicemia and the like by means of this parasite must be taken into account. In a word, a new department of disease etiology seems to be opened up by these observations.

THE NATURE OF ECLAMPSIA.

Eclampsia has been designated the "disease of theories." Because of the large number of hypotheses advanced to explain this condition, we infer that none is adequate, and such, indeed, appears to be true. In early times eclampsia was looked on as a disorder of the nervous system manifesting itself by a proneness to convulsions due to a less stable equilibrium of the nervous centers during pregnancy. Lever identified eclampsia with uremia. Spiegelberg said that the occurrence of ammonium carbonate in the blood was responsible for the convulsions. The Traube-Rosenstein theory explained eclampsia as a result of edema and anemia of the brain. Bacterial infection has been held as the etiologic agent by many, especially by the French, and several organisms, isolated from cases of eclampsia, have been described. Perhaps an equal number of observers have obtained negative results in this respect, and this fact, together with the lack of uniformity in the positive findings, leave this theory unsupported by direct proof. Riviere's theory of autointoxication was, for a time, considered favorably by many. He claimed, and this was substantiated by others, that during pregnancy there occurred in the blood an accumulation of a toxic substance, while coincident with this the urine became less toxic. Later work by Volhard, Stewart and others demonstrated the fallacy of these results. Others claim to have found substances such as leucomains and large amounts of globulin in the blood serum; these findings also lack confirmation.

The fetal origin of the possible causal toxic substance has been much discussed of late. The fact that lesions identical with those of the mother have been found in the fetus, together with the occurrence of convulsions in the child after birth, have been used as an argument in favor of this idea, but, as Williams states, the evidence does not indicate whether the toxins pass from the fetus to the mother or in the opposite direction.

The clinical manifestations and the morbid anatomy indicate that in all probability there is some toxic substance in the circulation which gives rise to the familiar degenerative changes found in the liver and kidneys and often in other organs. At least from what we know concerning the causation of such lesions as thromboses in the liver, necrotic changes in this and other organs, acute nephritis and the like, these changes are more rationally explained on this hypothesis than on any other. Wells¹ recently attempted to explain several conditions

closely related in their morbid anatomy, namely, chloroform poisoning, acute yellow atrophy, phosphorus poisoning, septicemias and puerperal eclampsia, by assuming an inhibitory action of the toxic substances in these diseases on the synthetic processes, but not on the autolytic processes of the liver, thus producing the destructive changes seen in this organ. Up to the present, however, it must be admitted that the source, nature or even presence of such a toxic body in eclampsia rests largely on a hypothetical basis. Experimental evidence is almost totally lacking.

On this point Liepmann of Berlin² claims to have been successful in demonstrating the presence of a toxin in the placenta of eclamptics which is not present in the normal placenta. In order to show this, he dries the placenta and, after reducing it to a powder, injects a suspension of this in salt solution intraperitoneally into rabbits. The results indicate marked differences in the toxicity of eclamptic and normal placenta. This toxin, he says, is extremely labile, highly toxic for rabbits, is firmly bound to the albumin molecule, and it has not been possible thus far to isolate it by chemical means. The placenta appears to be its place of origin, and from here the poison is distributed throughout the body. Experimentally, he has shown that the toxic substance, like tetanus toxin, has a marked affinity for the brain substance and, by contact with this tissue in a test-tube for a time, the toxic property is destroyed or neutralized. Likewise the liver retains considerable quantities of this toxin, as shown by its increased toxicity for animals. The changes in the kidneys are explained purely as secondary results produced by the circulating poison.

This experimental work appears to bear out what has been suspected for a long time, namely, the presence of a toxin with more or less specific effects on the brain, liver and kidneys. The work, if confirmed, of course, marks an advance in that it definitely localizes the origin of the poison. How or why it originates, its character, whether leucomain, bacterial toxin, or what, is not discussed, these questions being in the field of pure speculation as yet.

Evidently the proper therapeutic means in these cases, reasoning from the above facts, would be immediate delivery, and, as it has been demonstrated that in general this method is more efficient in the treatment than the expectant method, this may be used as further support of the theory of the placental origin of the disease.

THE PURE FOOD BILL.

We reproduce on page 815 the Pure Food Bill as amended by the House Committee on Interstate and Foreign Commerce. While it takes considerable space, the measure is such an important one that, we believe, our readers will be glad to see it in its completeness. It

will be noticed that it is the Senate Bill, and not the Hepburn bill as introduced in the House some time ago. In the bill as it passed the Senate, provisions were made for foods, liquors and drugs, but as amended only two classes appear, foods and drugs, liquors being classed with foods. Drugs are so defined as to take in not only those in the Pharmacopeia and National Formulary, but also "any substance or mixture of substances intended to be used for the cure, mitigation or prevention of disease of either man or other animals." Mixtures require "a statement on the label of the quantity or proportion of any alcohol therein, or of any opium, cocaine or other poisonous substances." This provision, of course, only affects the dangerous preparations; the fraudulent and those which contain substances which are deleterious when used for a length of time are not affected. The provision to check the dangerous preparations, however, is a long step forward, and is probably all that could be had at the present time.

The clauses affecting liquors have been modified to pacify the blenders so that they can, with certain limitations, continue their nefarious practice of making imitation whiskey, and the opposition of the whiskey trust will not be so bitter as before.

The most dangerous amendment, on its face, seems the most laudable. It is that which provides for a board of experts to determine the standard of any preparation; that is, for instance, if a certain preparation contains preservatives, it would be the function of this board to determine whether or not such preservatives are dangerous. This committee is to consist of five specialists, a toxicologist, a physiologic chemist, a bacteriologist, a pathologist and a pharmacologist. The provision will be found in Section 9. It will be noticed that in the first part of this section the Secretary of Agriculture is given authority to call on the committee on food standards of the Association of Official Agricultural Chemists and the committee on standards of the Association of State Dairy and Food Departments "and such other experts as he may deem necessary." In that which follows to the end of the section comes the danger. It will be noticed that any manufacturer can demand that his product be referred to this special board of experts; that the decision of this board is final, and that there is no appeal to the courts or to the Secretary of Agriculture, and that the board is responsible to no one. Neither is any discretion left to the Secretary of Agriculture to add to or to change the committee.

We hope our readers will look at this carefully and, if they are at all interested, we trust they will write to their congressman in regard to this particular provision. There is no objection to such a board, provided it is to aid the Secretary of Agriculture in coming to a decision, the same as it provided when he calls for the aid of the other committees referred to above.

If this amendment is allowed to stand as it is, it very seriously weakens the bill. It lessens the responsibility

² Münch. med. Wochschr., Nos. 15 and 51, 1905. Abstracts in THE JOURNAL, page 1888 of vol. XLV, and 761 of current volume.

by placing it in the hands of several men; it gives a splendid chance for the manufacturer to bring influence to bear, for it is well known that the greater the number the less the responsibility on each individual and the more opportunity for influence. We believe, however, that this particular provision will be modified when the attention of the House is directed to its danger.

"THE PHARMACOPEIA FETISH AND OTHER THINGS."

In its issue for March 10, under the above caption, the *Medical Record* comments on the papers, and the discussion following, presented at a medical meeting in Boston last January. It sadly abuses Dr. Billings,¹ who read the principal paper, but it does not reprint for the benefit of its readers what Dr. Billings said, since it could quote scarcely a paragraph without affecting some of its advertising patrons. Dr. Billings' paper is referred to as being practically the same as the one read at Portland, whereas entirely different phases of the nostrum evil were discussed. As we printed the article last week, however, our readers can judge for themselves of the merits of the article. They can also see whether or not Dr. Billings advocated the limitation of the use of medicines to those in the Pharmacopeia.

One of those who took part in the discussion is highly praised, because "he drew a sharp line of distinction between quack medicines exploited in the lay press and the secret pharmaceutical preparations advertised only to the medical profession—a distinction which is persistently ignored, to the detriment of pharmaceutical reform, by THE JOURNAL of the American Medical Association and its Council on Pharmacy and Chemistry." We regret that this allegation—so far as it refers to us—is correct. It is too bad, but we are not able to draw "a sharp line of distinction" between "patent medicines" and "the secret pharmaceutical preparations advertised only to the medical profession." We certainly can not draw this line, unless the *Medical Record* admits "patent medicines" to its advertising pages, which, of course, must not be thought of for a minute. And yet, as we turn to the advertising pages, we find Scott's Emulsion, Antikamnia, Syrup of Figs, Pond's Extract, Hydrozone, etc. When a nostrum is advertised to the public, we usually designate it as a "patent medicine," but when it is advertised in "ethical" medical journals we call it a "proprietary." To which class do these preparations belong? Where and what is the "sharp line" here? Kutnow's Powder, Vin Mariani and Angier's Emulsion are advertised in the lay journals in England, but we can easily see the "sharp line" here—the Atlantic Ocean.

1. We quote a sample: "Dr. Billings seems, however, to be a rather recent student of the good book [the Pharmacopeia] for he expresses sorrow that acetanilid . . . was made official in the last . . . Pharmacopeia," apparently unaware that it has been official for ten years." What Dr. Billings said was that he was "sorry that acetanilid was made official in the last Pharmacopeia as *Patris Acetanilidi Compositus*." He certainly knows that acetanilid was official before as *acetanilid*; his regret echoes that of Jacob, Solis-Cohen, and many others, that the Pharmacopeia has made acetanilid official in the form of a mixture as a substitute for the nostrums of the antikamnia class.

No, honestly, we can not see the "sharp line of distinction" not only as regards the method of advertising, but also as regards the general character of "secret proprietaries" and "patent medicines."

We are then given this unvarnished truth:

"If medical men will refuse to prescribe remedies the composition of which is unknown, the 'nostrum evil' will be at an end. But the physicians of this country are, as we have said before, not babies to be guided by a certain coterie of pharmacologists and therapeutic nihilists—a queer combination—whose slogan is, Back to the Pharmacopeia! and who seem to think that the way to reform the manufacturers of proprietary remedies is to class them with the makers of quack medicines."

This sounds very familiar, so much so that we are almost persuaded that it was written by a member of the Press Committee of the Proprietary Association of America. That committee tells us that if people did not want "patent medicines" they would not buy them, that the public is not made up of a pack of fools. And this all sounds so convincing, so absolutely unanswerable. But when this "argument" is used by the "patent medicine" men's press bureau the reply is made that the public is deceived and misled by the advertisements, and that the newspapers, the source of information for the people, are suborned by the "patent medicine" men and will not permit anything to appear against "patent medicines," and consequently the public is kept in crass ignorance of the actual facts and conditions. Is it possible that many medical men are also misled, because the medical journals, like the newspapers, are controlled by proprietary men? Banish the thought, at least so far as the *Medical Record* is concerned.

But, come to think of it, when the Council on Pharmacy and Chemistry showed that several of the preparations which the *Record* was carrying in its advertising pages were fraudulent, the *Record* did not inform its readers about it. And when, later, a letter containing the information was sent to the *Record*, it politely refused to publish the letter. The Commission on Anemia in Porto Rico, we are told, sent to the *Record*, for publication, a communication in which the commission gave proof that the vendor of Pepto Mangan had reprinted a part of its report, garbled in such a way as to make the ordinary reader believe that Pepto Mangan had proven satisfactory to the commission in the treatment of uncinariasis, whereas the report showed the opposite. Did the *Record* publish the communication? Not that we have seen.

Incidentally, it looks as though the *Medical Record* was not giving its readers the square deal.

One more quotation: "The *Medical Record* is heartily in favor of pharmaceutical reform, but it despairs of any progress so long as the cause is in the hands of the foolish and discordant Chicago missionaries." The word "discordant" is very good. We realize that this movement is discordant—it could not very well be otherwise.

But if the *Record* is really in favor of pharmaceutical reform, and does not like the methods that have been adopted by the American Medical Association, and which have been indorsed by medical societies all over the country, why does it not give definite reasons and suggest a better way? The *Medical Record* in favor of pharmaceutical reform? Is it possible so long as the greater part of its income is derived from such advertisements as Gray's Glycerine Tonic Comp., Pepto Mangan, Angier's Emulsion, Scott's Emulsion, Antikamnia, Kutnow's Powder, Seng, Phenalgin, Salacetin, Micajah's Medicated Uterine Wafers (a product of the Piso Consumption Cure people), Cactina Billets, Chionia, Neurosine, Neurilla, Germiletum, Bromidia, Dioviburna, Tongaline, Anasarcin, Pond's Extract, Sammetol, Echthol, Iodia, Papine, Ensoma, Echitone, Ammonol, Nutrolactis, Robert Hawley Goat Lymph Compound, etc.? If so, in what way would it suggest that reform be instituted? It acknowledges that something should be done. Will it suggest what? If the investigation of each proprietary article by men competent to do the work, the results of this investigation to be published later, is wrong, will the *Record* suggest why?

If it is ignorance on the part of the *Record* that impels it to confuse the real issue by intimating that the movement means limiting physicians to the use of those preparations which appear in the Pharmacopeia, we will enlighten it by saying that it is mistaken in its premises. If the movement means the limitation of the use of medicines to those which appear in the Pharmacopeia, it would be very foolish to spend money in the investigation of preparations that are not in that book and in the publishing of the book to be known as "New and Non-official Remedies."

We are very glad that the *Record* has spoken. We hope it will speak again. A free discussion of this nostrum question will do good. Let us have more of it. Publicity is what is wanted. Let us give the physician a square deal, however, by publishing all the facts.

ERA OF THE PHONOGRAPH.

In one of Mr. H. G. Wells' ingenious fancies he shows up a future condition of the world's progress—a very unpleasant one it must be said—in which books have had their day and literature is perpetuated by phonographs, or what are called the "babbling machines." While no one would wish to realize the future he portrays, it is easy to see how great an advantage to a certain limited class of unfortunates would be the application of this particular feature. This point is specially suggested by Dr. George M. Gould in a communication to *Science*, in which he shows how large a world it would open up to the blind were this plan adopted, especially with the more recent improvements made in the so-called telegraphone of Poulsson, which is said to be far superior to the modern phonographs and graphophones now in common use. The suggestion is still too recent to have been thoroughly carried out, but it will be strange if we

do not see some fruits of it in the adoption of such methods in the education of the blind in public institutions. The method necessarily has its limitations, and it may not entirely supplant, as he seems to think it will, the raised or embossed letter method used in books for the blind. But in any case it seems to indicate greatly enlarged possibilities of pleasure and profit for a deeply affected class.

THE BANQUET PERIL.

Several years ago THE JOURNAL had occasion to call attention to certain dangers incurred by banquet orators as specially illustrated by one or two notable instances. The dangers of public banquets do not appear to be entirely confined to those who have to undergo the cerebral congestion involved in after-dinner speeches. From time to time we hear of deaths occurring among those who took no prominent active intellectual part, and it is perhaps not too much to say that we are becoming somewhat accustomed to such casualties. In the city of Chicago alone one of the most prominent and public-spirited citizens succumbed not long since to the effects of an apoplectic attack incurred on such an occasion, and at a late Washington birthday banquet at one of the leading clubs two prominent citizens had to be carried out, one of whom has since died. There seems to be a sanitary question here involved that is worthy of consideration. While such serious casualties occur only among a very minute percentage of those actually present, there can be little doubt that the accompanying conditions have much to do with their production, and the question arises why they should occur at all. The participants in these banquets are men in the prime of life or past it and many of them are at a critical age or are suffering from arterial or cardiac disease and, therefore, in a physical condition favoring such accidents. They partake, however, of a hearty meal at a late and often unaccustomed hour under more or less exciting conditions, and often sit for hours in a more or less vitiated atmosphere, all of which are possible factors of sudden breakdown. In the social functions called "smokers," which have medical sanction in that medical men largely engage in them, it is easy to see how all these conditions may be aggravated. We must consider, also, that the glaringly evil effects are very probably not all that actually occur. There may be much suffering and perhaps some mortality that are really due to such occasions, though perhaps not properly credited and certainly not brought prominently before the public. The community suffers even by the loss of a very few valuable lives, and there is certainly in this matter an opportunity for medical consideration and prophylactic intervention in some way.

MODERN LONGEVITY.

According to William Curtis, the well-known newspaper correspondent, the actuaries of the large life insurance companies do not consider that the length of human life is increasing in the present conditions of our civilization. Admitting that there has been an improvement in the mortality of infants in the large centers of pop-

ulation this has not counterbalanced, in their opinion, the deteriorating influences acting on the vitality of those of riper years. Moreover, by the preservation of the weaklings in infancy the death rate in more advanced life has been increased, and this with the modern tendency to urban concentration and the intense strain of modern life has tended to decrease the average of longevity in spite of better sanitary conditions, the triumphs of medicine and surgery, the higher standards of living, and all the other conditions that might seem favorable to the prolongation of existence. While the death rate from diseases such as phthisis, and certain obviously preventable disorders like typhoid, has probably decreased, the increased mortality from heart troubles, kidney disorders, cancer and pneumonia, has more than made up the difference. It must be remembered, however, that the statistics of the large life insurance companies do not cover the whole population, but only a certain selected and provident class, and probably just that class that is most subjected to the high tension conditions of our modern civilization. It is not difficult to suppose that this class is perhaps of all others the least generally influenced by modern sanitary advances, and in making an estimate of the general average the figures it gives may be somewhat misleading, no matter how reliable they are for the special class they represent. The testimony of life insurance actuaries, however, can not be disregarded altogether as a warning against certain existing tendencies affecting the vitality of our population. Increasing luxury and speculation have much to account for what is ordinarily and superficially attributed, perhaps too exclusively, to the strenuous life. It is not hard work that kills so much as bad habits and neglect of ordinary hygienic living which no public sanitation can entirely counteract. That occupation itself is a life-saving factor is shown by the frequent rapid decline of health and early death in individuals who have retired from active business. Civilization saves the weaklings and interferes with natural selection and survival of the fittest, but it is not the struggle for life that is in itself most fatal. As a philosophic humorist has said with much truth, "Work is a snap. It is the intermissions that do up the nervous system."

A SERIOUS JOKE.

The newspapers last Sunday contained the announcement that Dr. Gregory, a member of the Legislature of Iowa, had introduced a bill authorizing the putting to death of incurables, idiots, etc. While we understand that the Doctor believes, to a certain extent, in the principles underlying the measure, he did not introduce it himself, but some other member did, more as a joke than anything else. The jokers had sent out their "story" in advance, and as a result Dr. Gregory has made himself famous. The bill was never considered seriously by the members of the Iowa Legislature and it was withdrawn, because, as our reporter remarks, its sponsors could not stand the severe criticism pouring in from all parts of the country.

Aortic Regurgitation in Childhood.—Dr. David Officer says that the cause of aortic regurgitation in children is nearly always vegetations resulting from endocarditis of rheumatic origin.—*Intercolonial Medical Journal of Australasia.*

Medical News

CALIFORNIA.

Tuberculosis Placarded.—The town of Selma has added tuberculosis to the list of diseases declared to be communicable and dangerous to the public health.

Expelled from Society.—Dr. John J. Gaynor, Eureka, was found guilty of unethical advertising and solicitation of obstetrical cases, February 13, and was expelled from the Humboldt County Medical Society by a vote of 14 to 1.

Election of Officers.—The Pomona Valley Medical Society, a branch of the Los Angeles County Medical Association, has elected Dr. Frank W. Thomas, Claremont, president; Dr. Clarence G. Toland, Pomona, secretary, and Dr. Frank Garelon, Pomona, counselor.

Dr. Baruch Only a Volunteer.—Dr. Simon Baruch notifies THE JOURNAL that he has not taken charge of the new bathhouse at Paso Robles, as he has neither the legal authorization nor the desire to practice medicine in California. His mission is simply that of a volunteer to organize a national health resort which will pay special attention to hydrotherapy and balneology.

Annuls Action of State Board.—The Supreme Court has annulled the action of the State Board of Medical Examiners revoking the license of "Dr." Jessie C. Hewitt, Los Angeles, who advertised a cure for cancer. The court annulled the order of revocation on the ground that the medical law is vague, indefinite and uncertain.

Prohibits Distribution of Samples.—The board of trustees of Selma has passed an ordinance providing that any person who distributes samples of any patent or proprietary medicine in the town, by delivering samples or small quantities thereof to minors, or by leaving samples or quantities thereof on the streets or in the yards, or in and about any buildings of said town, or who advertises any medicine or drug of medicinal preparation, by leaving samples or small quantities thereof, where the same are likely to fall into the hands of or be picked up by any minors in said town, shall be guilty of a misdemeanor.

Personal.—Dr. Robert E. Rooney of Auburn is ill with pneumonia. —Dr. H. M. Cox has been reinstated as physician of San Luis Obispo County, vice Dr. Joseph S. Jackson. —Dr. Henry M. Fine, Oakland, has succeeded his father, Dr. Andrew Fine, as examiner for the United States pension bureau. —Dr. J. Myles Crenshaw, Redlands, has resigned as physician of San Bernardino County and his place has been filled by Dr. Paul S. Anderson, San Diego. —Dr. Eli A. Kusel has been made a member of the board of health of Oroville. —Dr. and Mrs. George M. Converse, San Francisco, will attend the International Medical Congress in Lisbon and spend several months in travel in Europe.

CONNECTICUT.

January Deaths.—During January 1,331 deaths occurred, 13 more than in December and 81 less than in January, 1905. The rate was equivalent to an annual mortality of 16.2 per 1,000. Pneumonia caused 200 deaths; diseases of the nervous system, 171; heart disease, 136; consumption, 105; accidents and violence, 179, and influenza, 41.

Infectious Diseases.—During January 562 cases of measles were reported in 62 towns; 157 cases of scarlet fever in 39 towns; 7 cases of cerebrospinal meningitis in 3 towns; 159 cases of diphtheria in 37 towns; 86 cases of whooping cough in 10 towns; 46 cases of typhoid fever in 21 towns, and 37 cases of consumption in 20 towns.

Election of Officers.—The New Haven County Medical Society has elected the following officers: President, Dr. Leonard W. Bacon, Jr.; vice-presidents, Dr. Henry W. Ring and Dr. Edward M. McCabe; secretary, Dr. Willis E. Hartshorn; treasurer, Dr. Robert E. Peck, and executive committee, Drs. Jay W. Seaver and Stephen J. Maher.

Personal.—Dr. Archibald McNeill, who has been bacteriologist of the New Haven board of health for several years, has resigned. —Dr. George S. Ford has been appointed fire department surgeon of Bridgeport, vice Dr. Elmer F. Blank. —Dr. C. Lincoln Banks has been chosen physician of the Bridgeport police department, vice Dr. J. Murray Johnson.

Illegal Practitioner Fined.—"Prof." G. Herman Lawson, Hartford, who is at present under charges for alleged violation of the medical practice act, was fined \$60.70 for drunkenness, breach of the peace and assault. He is held in \$200 bonds on the charge of practicing medicine without a license. —In the

case of the Hartford County Medical Society vs. M. F. Adleman for illegal practice of medicine, the defendant was adjudged guilty and was fined \$100.

Donations to Hospitals.—By the will of John Weed of New York \$50,000 is bequeathed to the Stamford Hospital, to found a branch hospital for the treatment of contagious diseases and to pay for the care and the treatment of the sick poor.—Mrs. Charles P. Taft of Cincinnati has given \$15,000 for the enlargement of the infirmary of the hospital of Yale University.—Mrs. Julia C. Griswold has given \$5,000 from the Griswold fund to endow a free bed at the Litchfield County Hospital.

ILLINOIS.

Measles and Mumps.—Argosa has an epidemic of measles, with 3 deaths.—Waukegan reports that 4 teachers and 175 school children are ill with mumps.

Eye and Ear Infirmary Staff Under Civil-Service Laws.—In an opinion rendered March 6, the attorney general holds that the medical staff, including internes, of the Illinois Charitable Eye and Ear Infirmary, Chicago, comes under the classified list. The civil-service commission was not clear on this point, as the medical staff receives no compensation.

Eye and Ear Men Meet.—A meeting of the Eastern Illinois Ophthalmological and Otological Society was held March 6 in Decatur, to complete organization, approve the by-laws and elect officers. The following officers were elected: President, Dr. James W. Sanders, Decatur; vice-president, Dr. Benjamin Gleason, Danville, and secretary-treasurer, Dr. Charles P. Hoffmann, Danville. This society embraces the cities of Danville, Mattoon, Decatur, Champaign, Bloomington and Paxton, and has a membership of 21.

Fears Contamination of Water Supply.—On behalf of the State Board of Health, Dr. James A. Egan has filed objections to a further extension of Waukegan's sewer system emptying into Lake Michigan, unless the septic tank or other purifying method is employed. In a letter to the local board of health he states that the state board has for some time been investigating the contamination of lake water by city and factory sewerage on complaint of Lake Forest and other places to the south, whose water supply appears to have been contaminated. He characterizes Waukegan's plan to run more sewage into the lake as dangerous.

Chicago.

Hospital Will Build.—A building permit has been issued to the Chicago Union Hospital to erect a four-story brick building to cost \$35,000.

Deaths of the Week.—During the week ended March 10, 607 deaths were reported, equivalent to an annual death rate of 15.44 per 1,000. Pneumonia caused 93 deaths; consumption, 76; heart diseases, 46; nephritis, 45; violence including suicide, 44; and nervous diseases, 35.

Extortion Case Settled.—In the case of Dr. F. H. Stewart and John Burns, charged with being parties to a confidence game whereby \$40 was obtained from Andrew Vick, the defendant Stewart returned the amount which had been paid, and the case was dismissed, at the request of the plaintiff.

Scarlet Fever Threatening.—There is an alarming increase in scarlet fever, 124 cases being reported last week as compared with 113 for the previous week and only 21 during the corresponding week of 1905. Thus far this year 84 deaths from this disease have been reported as compared with 19 during the similar period of 1905.

Care of Epileptics.—Dr. William P. Sprattling, medical superintendent of the New York State Colony for Epileptics, Sonoma delivered an address on the "Public Care of Epileptics" at a meeting held at the Chicago Woman's Club, March 14, under the auspices of the Children's Hospital Society, to advocate a movement for the establishment of a state colony for epileptics in Illinois.

MARYLAND.

Personal. Dr. Charles M. Ellis, Elkton, president of the national bank there, and past president of the Medical and Chirurgial Faculty of Maryland, was operated on at Johns Hopkins Hospital for appendicitis by Dr. Halsted, March 8. He is doing well.

Hospital Needed for Colored Insane.—A bill has been introduced into the legislature, it is said, under the auspices of the state lunacy commission, to establish a state hospital for in-

sane colored persons, to be known as the Third Hospital for the Insane. The bill creates a board of directors to consist of the members of the board of public works and six others to be appointed by the governor. The sum of \$75,000 is appropriated for land and buildings and \$25,000 a year for support.

Vital Statistics.—Dr. William L. Lewis, Kensington, health officer for Montgomery County, reports 408 births and 304 deaths during 1905. Tuberculosis caused 52 deaths; pneumonia, 30; nephritis, 19; heart disease, 16; typhoid fever, 12; malignant disease, 12, and diphtheria, 2. He notes that tuberculosis was the cause of deaths in 25 per cent. of the colored decedents and of only 7.5 per cent. of the white decedents; nearly 38 per cent. of the total deaths among negroes was due to disease of the lungs.

Baltimore.

Health Report.—The mortality from consumption (38) ran ahead of that from pneumonia (34) last week; 5 deaths were credited to whooping cough, and 6 cases of smallpox were reported.

To be Extradited.—Mrs. Emma Haslem, who jumped her bail of \$1,500 about three years ago, while charged with complicity in a criminal operation, has been arrested in Minneapolis and will be brought back under extradition papers. Dr. William B. Hawkins, who was tried for the same case, is now serving a ten years' sentence in the penitentiary.

Tuberculosis Fumigation.—The board of estimates has appropriated \$21,000 for fumigation against tuberculosis. It will be under the direction of the health commissioner. All houses from which tuberculous patients have been moved or where they have died will be treated before they can be occupied. It is estimated that there are 2,500 houses requiring such fumigation.

Personal.—Dr. John M. T. Finney has rented a cottage at Jamestown, R. I., for the summer.—Dr. Harry Friedenwald has been re-elected president of the Baltimore branch of the *Alliance Israélite Universelle*, and Dr. Joseph Blum has been elected a director.—Dr. Edward Lindon Mellus is now in Sicily.—Dr. Albert J. Underhill was installed as fire department surgeon, March 10, vice Dr. Edward Geer, deceased.

The Harriet Lane Home for Invalid Children, founded by the late Harriet Lane Johnson, niece of President Buchanan, will be located on the Johns Hopkins Hospital grounds. The bequest amounts to several hundred thousand dollars. The home is for white children, with preference for boys and those living in Maryland, Pennsylvania and the District of Columbia. The home is to pay the cost of operating its buildings and the agreement is to run for twenty years.

MASSACHUSETTS.

Milk Dealers Fined.—Twenty-four milk dealers were recently fined in Boston for selling milk not up to the required standard. Samples had been collected since January 15.

District Nurses' Work.—The District Nursing Association of Boston employs 20 nurses, of whom 15 are district nurses on regular duty. They cared for 9,212 cases last year, making 68,755 visits. There are three undergraduate assistants and two nurses working in the public schools.

Not Influenza but Typhoid.—The board of health of Medway has been sharply rebuked by Dr. Charles Harrington, secretary of the State Board of Health, for permitting the concealment of typhoid fever. Thirteen cases in one boarding house were diagnosed and treated as influenza.

Dinner to Bowditch.—Dr. Henry P. Bowditch of Harvard University Medical School was tendered a dinner by the Bowditch Club at the Copley Square Hotel, March 6, at which about fifty members were present, and at which the guest of honor was presented with a solid silver loving cup by the club.

Publication of Health Bulletin.—An act has been introduced in the legislature providing that the State Board of Health shall publish every month, in two daily papers in Boston and two daily papers in each county, a report of the analyses made by the board during the preceding month of adulterated food, drugs and liquors, stating that name and nature of the adulterated article, the name of the manufacturer, and the number of prosecutions made or begun by the board under the provisions of sections 16 or 27 of chapter 75 of the revised laws.

New Trustees.—Mayor Fitzgerald of Boston has appointed on the new board of Consumptives' Hospital trustees, who will direct the expenditure of the \$150,000 appropriated July 3, 1901: Edward F. McSweeney for five years; Miss Elizabeth

A. Power for four years; Dr. James J. Minot for four years; Miss Isabel Hyman for three years; John E. Potts for two years; Dr. John F. O'Brien for two years; and Herbert F. Price for one year. A special law is before the legislature to permit this board to hire 100 beds in private institutions at \$5 per week until the new hospital can be constructed and fitted for use.

What Constitutes Practice of Medicine. Vigorous efforts are being made to secure a more definite statement in the Laws of Massachusetts as to what constitutes "practice of medicine" and hence render its practitioners amenable to the State Board of Registration. Opposition to any such regulation comes from followers of Eddyism, mind cure, hypnotism, massage and the like. District Attorney Moran failed to secure the passage of his bill looking to the regulation of abortionists, recently quoted in THE JOURNAL. The osteopaths are earnestly seeking the establishment of a separate board of registration for their school.

NEBRASKA.

Physician's Office Burned.—The office of Dr. Charles O. Petty, Beaver Crossing, was destroyed by fire January 24 with a loss of \$2,500.

Stricken with Apoplexy.—Dr. Benjamin F. Crummer, Omaha, former president of the Nebraska State Medical Society, was attacked with cerebral hemorrhage, March 12.

Methodist Hospital Assured.—The entire \$35,000 necessary to obtain the \$30,000 donation of Dr. August F. Jonas, Omaha, to the Methodist Hospital of that city, was completed March 1.

Awarded Damages.—Dr. Charles Rosewater, Omaha, on February 4, was awarded \$11,000 damages against the Illinois Central Railroad for injuries received by being run down by a train on that road Jan. 2, 1904. He brought suit for \$20,000, claiming permanent injuries.

Personal.—Dr. H. L. Wells, West Point, has been appointed physician of Cuming County. Dr. Silas G. Allen, Clarkson, has been appointed coroner of Colfax County, vice Dr. Edward C. Jungbluth, Schuyler, deceased. Dr. William R. Cornelius, Columbus, has been, for the third time, appointed physician of Platte County.

County Medical Society Election.—At the annual meeting of the Omaha-Douglas County Medical Society, Dr. Warren H. Stabaugh, South Omaha, was elected president; Dr. Richard C. Moore, Omaha, vice-president; Dr. Joseph M. Aikin, Omaha, secretary; Dr. Millard Langfield, Omaha, treasurer, and Dr. Andrew B. Somers, Omaha, member of the board of censors.

Faculty Changes.—The University of Nebraska, Medical Department, announces the following changes in the faculty: Dr. D. Francis Lee has been made professor of materia medica; Dr. Mattie Laughlin Arthur, instructor in obstetrics; Dr. Charles W. Pollard, adjunct professor of obstetrics, and Ernest Clifford Page, lecturer on medical jurisprudence. Drs. Ewing Brown and George B. Dandy have resigned.

Mortality Statistics.—The State Board of Health reports 5,470 deaths during 1905, of which the largest number, 724, occurred in October and the smallest number, 293, in August. Heart failure is charged with 532 deaths; tuberculosis with 362; cancer with 245; apoplexy with 200; nephritis with 165; paresis with 147, and typhoid fever with 109. During the year there were 76 suicides; 43 individuals were accidentally burned to death, the same number killed by firearms, and 35 persons were drowned.

NEW YORK.

Throat Disease Prevalent.—More than a thousand persons in Yonkers are suffering from a contagious disease of the throat, having symptoms somewhat similar to those of diphtheria. It is the opinion of the health officer that the affection is due to atmospheric conditions.

Want Local Health Commissioner.—Bills were introduced into the senate and assembly creating the office of health commissioner for the Boroughs of Brooklyn and Queens, thus taking from Commissioner Darlington control of the health department in those two boroughs. The bill has the indorsement of Dr. William F. Campbell, president of the Kings County Medical Society; Dr. J. W. Fleming and Dr. J. C. Hicks.

Ulster Water Supply Near.—A bill intended to compensate the people of Ulster County against any possible loss by reason of New York City going there for water and permitting of indirect damages to real-estate owners and also compelling New York City to rebuild more than half the system of Kingston which will have to be torn up in laying New York pipes, will make it possible for both the city and the county to reach a final agreement.

Bills to Help Sick Poor.—The Assembly cities committee held hearings on March 6 on bills affecting the plans of the city for the relief of the sick poor. One was the Wiedenmeyer bill, which prohibits New York City from establishing a consumptive sanatorium on Staten Island. Robert W. Hedberg, commissioner of charities, spoke in behalf of the city, showing how necessary it was that the consumptives of the city should be adequately taken care of, and that local prejudice should not be allowed to interfere with this work. The hearing on the Tompkins bill authorizing New York City to establish a recreation colony for convalescents and sick persons on Long Beach developed the fact that the town of Hempstead was anxious to hold Long Beach for speculative purposes. Drs. J. W. Barnard of Bellevue and Allied Hospitals; S. S. Goldwater, superintendent of Mount Sinai Hospital, and others urged the humanitarian side of the question, and consequently the bill is to be amended to have the colony known as a recreation park under the jurisdiction of the park department.

New York City.

Harvey Society Lecture.—The thirteenth and last lecture for the year in the Harvey Society course will be delivered by Prof. W. H. Howell of Johns Hopkins University at the New York Academy of Medicine, March 17, at 8:30 p. m. Subject, "The Cause of the Heart Beat."

Personal.—Dr. Henry Russell was quite severely burned about the face and hands while trying to extinguish a fire in his office. He was taken to Roosevelt Hospital. Dr. M. E. Lewis, interne of the first surgical division at Bellevue Hospital, is confined to his room and it is feared that he has contracted diphtheria.

Adulterated Milk. The permit of a large dairy company was revoked by the board of health after the report of the chief sanitary inspector had been submitted. The milk was not tampered with in the country or at the stations, but at a large milk depot in this city, where chronic adulteration on a large scale was cleverly carried on.

After Doctors Who Do Not Report.—The health department is after Brooklyn physicians who do not report contagious diseases which they attend. The increase in the number of cases of measles in Brooklyn has shown that physicians are not diligent in reporting cases. It is stated that hereafter negligent physicians will have to make their explanations in court.

Special Lectures.—Dr. L. Duncan Bulkley will give four special lectures at the New York Skin and Cancer Hospital, Second Avenue and Nineteenth Street, March 21 and 28, and April 4 and 11, in the Out-patients' hall of the hospital at 4:15, on "The Principles and Application of Local Treatment of Diseases of the Skin." These lectures are free to members of the medical profession.

Can Not Stop Steam Whistles.—In regard to the complaints of residents of Riverside Drive against the blowing of whistles in the harbor and the request that additions be made to the sanitary code to allow prosecution of the offenders, the health board has decided that the present code covers the question as fully as the city can regulate it and that any further action will have to be taken by the federal government.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended March 3, 1,903 cases of measles, with 45 deaths; 475 cases of tuberculosis, with 225 deaths; 105 cases of diphtheria, with 61 deaths; 222 cases of scarlet fever, with 5 deaths; 37 cases of typhoid fever, with 7 deaths; 29 cases of cerebrospinal meningitis, with 21 deaths, and 180 cases of varicella, making in all 3,251 cases, with 364 deaths.

New Metropolitan Hospital.—At the annual meeting of the Metropolitan Hospital and Dispensary board, March 8, it was decided to purchase a site for a new building at once. The following gave \$500 each: L. Loipsiger, R. F. Rudell, I. Gottlieb, C. Holborn, M. Featherston, S. Weiner, L. D'Angelo, G. A. Senel and H. G. Ramsperger and S. Childs, and in all \$5,000 was subscribed. The building committee was authorized to sell the present hospital site and the woman's auxiliary was requested to obtain the necessary furnishings for the new hospital.

Raid on Spitters.—It is said that for the past three months from eight to ten arrests have been made each day for spitting, but little attention was paid to the matter, so the health department decided to call the attention of the public to this class of offenders by arresting men in the theater district. On the evening of March 8, nine arrests were made in the lobbies of theaters and the offenders held in \$500 bail for appearance in court. Only a few were fined, as it was held that the theater lobbies were public places within the meaning of the sanitary code and that cuspidors should have been provided.

Nurses and Hospitals Criticised.—At the meeting of the alumni of Bellevue Hospital Medical College at the Yale Club, Dr. W. Gilman Thompson was especially severe on the nurses, stating that the profession was in the hands of a "nurses' trust." Other speakers on this occasion pointed out the desirability of establishing hospitals at convenient points throughout the city which could be reached readily in case of necessity. Dr. Russell Bellamy made a plea for cheaper hospital construction. Hospitals should be built like barracks, as a distinguished English physician had said, and should be burned down once in every five years and then built over again.

Warned Against Malpractice.—The postal authorities some time ago decided to start a campaign against persons guilty of malpractice in this city who advertise and use the mails for this purpose. Postoffice Inspector Snow of Boston, who recently conducted a similar campaign with success, was ordered to come to New York to take charge. He found in several papers advertisements of a character that left no doubt as to the advertiser's intent. The County Medical Society's detectives furnished, in some instances, practically legal proof. More than fifty of the best known of the advertisers were asked to call at the Federal Building and see Inspector Snow. The majority of the callers were women; all were warned, and not a few will leave the city. Some arrests may be made.

Measles and Diphtheria.—Dr. Darlington, the health commissioner of this city, has appealed to the people of New York, asking that every precaution be taken to prevent the spread of measles and diphtheria, since both diseases have been increasing rapidly in all sections of the city. In January and February there were 616 more cases and 77 more deaths from diphtheria than during the same period of last year. The record of March, 1904, when 7,000 cases were reported, will be broken unless the epidemic is curbed. In February, 6,310 cases of measles were reported, and during the first week in March, 1,899 more. Dr. Darlington has advised a generous use of antitoxin even before the examining physician has reached a decision. The report of the health department, covering a period of thirteen weeks, shows that Ellis Island is one of the most fertile spots for the breeding of disease in the city. There were 168 cases of measles taken from the island in the period above mentioned.

OHIO.

Physician Fined.—Dr. Alexander Grytza, Toledo, was fined \$50 and costs, February 24, for practicing without a license.

Byron Stanton's Semi-Centennial.—Twenty professional friends and associates of Dr. Byron Stanton, Cincinnati, celebrated the fiftieth anniversary of his entrance into the medical profession, February 23, with a banquet, at which a loving cup was presented to Dr. Stanton by Dr. N. Pendleton Dandridge on behalf of those present.

Want Hospital Instead of Library.—Twenty-one hundred of the citizens of Mansfield have signed petitions requesting that the Carnegie Library building, now in course of erection, be made into a city hospital and that the \$10,000 already advanced by Mr. Carnegie be returned to him unless he is willing to have the building used as a hospital.

Fires.—Two fires have recently occurred in the Branch Hospital, Cincinnati.—A fire from a defective grate in the apartments of the superintendent of Longview State Hospital in Cincinnati caused a loss of \$1,000.—The office of Dr. Minor M. Jacobs, Hamilton, was destroyed by fire February 14, with a loss of about \$1,400, partially covered by insurance.

Academy Meeting.—At the regular meeting of the Cincinnati Academy of Medicine, March 5, the following officers were elected for the ensuing year: President, Dr. John E. Greiwe; vice-presidents, Drs. Henry W. Bettman and Ellen McCarthy; secretary, Dr. Stephen E. Cone; treasurer, Dr. Alexander G. Drury; trustees, Drs. N. Pendleton Dandridge, J. F. Hesse and Asa B. Isham; and censors, Drs. Edwin W. Mitchell, E. Gustav Zinke and David I. Wolfstein.

Appointments by the Board of Public Service, Cincinnati.—Physician to the workhouse, Dr. J. A. Flanagan, vice Dr. Otto P. Geier, salary \$100 per month; physician to House of Refuge, Dr. Moses Salzer, vice Dr. F. A. Kautz, salary \$37.50 per month; physician to City Infirmary, Dr. J. M. Adams, \$112.50 per month; medical superintendent of the Branch Hospital for Consumptives, at \$100 per month, and contagious disease expert to the health department at \$75 per month, succeeding Dr. B. F. Lyle, Dr. Albert Falter.

Tuberculosis Hospital Has Waiting List.—The Cincinnati Branch Hospital has become so popular among the tuberculous poor of the city that accommodations can not be supplied for all applicants and quite a large waiting list has arisen. For

the most part, those waiting are being treated at their homes, but, unfortunately, not a few have to be kept in the main building of the hospital. The failure of the board of public service to provide accommodations for the tuberculous poor, if necessary, by means of tents, is defeating the purpose for which the branch was built, the separation of the consumptives from those afflicted with other diseases, in this way preventing the spread of the disease.

Condemns Drink Cure.—The Montgomery County Medical Society, at its meeting March 2, expressed its disapproval of the exploitation by the lay press of the Oppenheimer method, which is claimed to cure drunkenness. The censors in their report noted that the exploitation of this so-called cure provided for a committee of prominent citizens which did not contain the name of a single member of the medical profession, but was made up of eight clergymen and nine other gentlemen, who presumably were not qualified to pass on the correctness or incorrectness of the claims made by the proprietors of this alleged cure. The censors advise the society to place the stamp of disapproval on this attempt of mercantile medicine to obtain a standing in the community under the cloak of charity.

Personal.—Dr. Alonzo B. Walker, Canton, has been elected president of the Union Medical Association of the sixth councilor district.—Dr. Wm. A. Dickey, Toledo, was struck by a car, February 25, and rendered unconscious.—Dr. Milton V. Cunningham has been appointed city physician of Youngstown, vice John J. Thomas.—Dr. Charles S. Hamilton has succeeded Dr. Starling Loving as dean of Starling Medical College, Columbus.—Dr. J. Hollis Ward, Vinton, is seriously ill with pneumonia at the home of his parents in Columbus.—Dr. Martin Stamm, Fremont, has been elected president of the Sandusky Medical Society, vice Dr. Robert H. Rice, Fremont, deceased.

—Dr. Edward Reinert, Columbus, was operated on for appendicitis, February 28.—Dr. Charles A. Cooperider, Columbus, was made seriously ill by an overdose of a drug taken to relieve pain, March 4.—Dr. Charles M. Showman, North Baltimore, is seriously ill with appendicitis.

Celebrate Twenty-fifth Anniversary.—The following ten Cincinnati physicians celebrated the twenty-fifth anniversary of their graduation in Medicine, February 28: Dr. F. W. Langdon, neurologist, Miami Medical College, Cincinnati Hospital and Cincinnati Sanitarium; Dr. Frank W. Harmon, superintendent Longview Insane Asylum; Dr. Allen B. Thrasher, laryngologist, trustee of the Cincinnati Hospital; Dr. John L. Davis, medical director Union Central Life Insurance Company; Dr. Edward S. McKee, gynecologic department of the Medical College of Ohio for twenty-three years; Dr. George A. Fackler, of the staff of Cincinnati Hospital; Dr. Benjamin F. Clark, surgeon of the Big Four Railway and Cincinnati fire department; Dr. David DeBeck, ophthalmologist, Medical College of Ohio and Good Samaritan and St. Mary's hospitals; Dr. John H. Blau, practitioner of Covington, Ky.; Dr. N. Irwin Scott, practitioner of Norwood, and Dr. Adolph Grimm, practitioner of Cincinnati, and for many years in the laryngological department of the Medical College of Ohio.

PENNSYLVANIA.

Philadelphia.

Announcement.—The annual meeting of the American Society of Tropical Medicine will be held in Philadelphia, March 21.

Bequest.—By the terms of the will of the late Rev. Benjamin H. Sanderlin, the Methodist Hospital will receive \$5,000 for the endowment of a free bed to be known as "The Memorial Methodist Episcopal Church bed, donated by the Rev. Benjamin H. Sanderlin and wife."

Non-Suit Accepted.—After a partial trial in Common Pleas Court No. 1, March 9, the action brought by Emil Krueger against Dr. H. Augustus Wilson to recover \$10,000 damages for injuries in an automobile accident, was ended by counsel for the plaintiff suffering a voluntary non-suit.

Hospital Reports.—During February the Methodist Hospital admitted 92 patients and treated 454 new patients in the various outdoor departments.—The Polyclinic Hospital admitted 103 patients to the wards and treated 1,598 new patients in the dispensaries. In all 7,791 visits were made to the out-patient departments.

Personal.—Dr. and Mrs. J. Norman Risley are in England. Dr. and Mrs. Boardman Reed have returned from Europe and are now in California.—Dr. William G. Niles, resident physician in the Presbyterian Hospital, is seriously ill.—Dr. James Anderson is confined to his house with influenza.—Dr. Hiram Langrehr was thrown from his bicycle, March 6, and severely injured.

Discussion on Quackery.—On March 19 the Philadelphia Medical Jurisprudence Society will discuss, "Quackery: What Are We Going to Do About It?" Hon. Champe S. Andrews, counsel of the New York County Medical Society, will deliver the opening address, and Philadelphia physicians hope that this meeting may mark the start of a movement against the horde of quacks now preying on the Philadelphia public that will equal the success of that against those of other culprits, the abortionists.

Work of Visiting Nurses.—At the annual meeting of the Visiting Nurses' Society it was reported that the number of new cases visited aggregated 2,311, and the number of old cases visited was 121, making the total number of cases visited 2,432. The number of visits paid was 38,282. The school nurses' report is as follows: The number of schools assigned, 6; number of treatments given to old cases, 6,692; number of new cases, 1,708; number of children attended at home, 476; number of visits to homes, 843. Mrs. Henry C. Lea was elected president.

Lectures and Addresses.—Dr. John B. Deaver addressed the Stillé Medical Society of the University, March 2, on "The Relation of the Physician to Modern Surgery."—Dr. Edward C. Spitzka, New York City, delivered a free public lecture on "The Brain" at the rooms of the American Philosophical Society, March 16.—Dr. M. P. Ravenel of the state veterinary board addressed the Pennsylvania State Veterinary Medical Association on "Hydrophobia" at the annual meeting in this city, March 6.—Dr. Ward Brinton, secretary of the Pennsylvania Society for the Prevention of Tuberculosis, delivered a lecture on "Consumption," March 8, at St. Ambrose's Protestant Episcopal Mission.

Health Report.—The total number of deaths reported for last week numbered 633. This is a decrease of 37 from those reported the week before, and an increase of 34 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 35; measles, 12; diphtheria, 10; consumption, 76; cancer, 13; apoplexy, 15; heart disease, 45; acute respiratory disease, 122; gastritis, 8; enteritis, 36; Bright's disease, 48; premature birth, 19; accidents, 29; marasmus, 2. There were 357 cases of contagious disease reported, with 52 deaths, as compared with 469 cases and 56 deaths in the previous week. There was a marked decrease in the cases of typhoid fever reported during the week, the number being 231 as compared with 352 reported in the previous week. The situation concerning typhoid in relation to its distribution is the same as it has been during the past six months, the bulk of the new cases being reported from wards comprising the northeastern section of the city, which receives the water supply by direct pumpage from the Delaware River. Measles is still prevalent, the number of cases this week reaching 630, or 6 more than those reported last week. Notwithstanding the large number of cases the death rate is comparatively small, 12 deaths being reported from this disease during the week.

TENNESSEE.

Attempt at Suicide.—Dr. Edward P. Gould, Chattanooga, formerly of Royal Center, while temporarily deranged from overwork, attempted suicide January 9 by cutting his throat. Fortunately, aid came in time and he has recovered.

Found Guilty of Murder.—Dr. Y. Safford Troyer, Memphis, charged with murder in the second degree on account of criminal malpractice, was found guilty February 10 and sentenced to imprisonment for ten years in the penitentiary.

Ground Broken for New College.—On March 1 the ground for the new Memphis College of Physicians and Surgeons was formally broken in the presence of the faculty and students by Dr. Maximilian Goltman. The building will cost about \$60,000 and will be ready by September 1.

New Hospitals. Lincoln Memorial Hospital, Knoxville, erected by the Tennessee Medical College at a cost of \$10,000, was opened February 12. In addition to four large wards it has two private wards, an obstetrical ward, an operating pavilion, nurses' ward, etc.—Dr. William J. Matthews has opened a private hospital in Johnson City.

Society Meetings. The Rutherford County Medical Society held its annual meeting in Murfreesboro, Dec. 6, 1905. The following officers were elected: Dr. James B. Murfrees, Sr., Murfreesboro, president; Dr. James J. Rueker, Ayerall, vice-president; Dr. Rufus Pitts, Murfreesboro, secretary and treasurer; Dr. Enoch H. Jones, Murfreesboro, censor; Dr. V. K. Farthman, Murfreesboro, delegate to the state association, and Dr. Harry C. Rees, Murfreesboro, alternate.—The Union City Academy of Medicine was organized at that place Janu-

ary 26. Dr. D. M. Pierce was elected president; Dr. J. M. Rippy, vice-president, and Dr. Marion A. Blanton, secretary.—Greene County Medical Society has elected the following officers for the ensuing year: President, Dr. H. H. Ruble, Greeneville; secretary, Dr. S. Walter Woodard, Greeneville. The society is in prosperous condition and includes in its membership the majority of the eligible physicians in the county.

Personal.—Dr. Marcus Haase, Memphis, formerly secretary of the local health board, who resigned in order to pursue his studies in Johns Hopkins and in Berlin, was given \$1,200 by a number of his friends, January 11.—Dr. John C. Bell has been appointed chief sanitary inspector of the Memphis board of health, vice Dr. James L. Andrews, promoted to secretary of that board.—Dr. W. Frank Glenn has been elected president of the board of health of Nashville.—Dr. George P. Edwards, Nashville, has sufficiently recovered from his recent operation to be removed to his home.—Dr. and Mrs. E. R. Hochstetter, Ridgedale, are spending the winter in California.—Dr. E. E. Shivers has been made surgeon for the Louisville & Nashville Railway and assistant surgeon for the La Follette Coal, Iron & Railway Company at Somerville.—Dr. John R. Rathmell has been made dean of the Medical Department of Grant University, Chattanooga, vice the late Dr. Edward A. Cobleigh, and Dr. William G. Bogart has succeeded Dr. Rathmell as secretary of the faculty.—Dr. Rufus E. Fort, Nashville, has been appointed a member of the State Board of Health, vice Dr. William J. McMurray, deceased.—Dr. Thomas H. Marable, Clarksville, has been appointed local surgeon for the Illinois Central Railway Company.—Dr. William B. Rogers has been appointed president of the Memphis board of health.

TEXAS.

Medical Books for Library.—Two hundred volumes of medical books have been bequeathed to the Carnegie Library, Houston, by the late Dr. William H. Harrison, Brunner.

Malpractitioner Pardoned.—Dr. Hannah Reum, El Paso, who is serving a penitentiary sentence of two years on the charge of criminal malpractice, has been pardoned because of the critical condition of her health.

Railway Hospital at Sherman. The management of the Frisco System has issued an order designating St. Vincent's Sanitarium, Sherman, as the general hospital for the southwestern division of the system.

Fires.—The residence of Dr. Aaron L. Jones, Prairie Dell, was destroyed by fire January 9. Very little was saved and no insurance was carried.—The building at Melissa, owned by Dr. J. E. Hunter and occupied by Dr. A. V. Rutledge, was destroyed by fire, January 20.

Smallpox.—Several cases of smallpox are reported in and around Madison.—A number of cases have been reported in San Angelo.—The public school at Frost has been closed on account of smallpox.—Six cases of smallpox are reported in the southeastern part of Comanche County.—On February 14 several new cases of smallpox were reported at Boyd.

Gift to Dr. Tabor.—Before State Health Officer Tabor left for Europe eighteen of the leading citizens of Galveston forwarded him a check for \$1,000 and steamship transportation for himself and wife in token of their appreciation of the efficient work of Dr. Tabor in keeping Galveston and its trade territory free from yellow fever.

State Society Meeting.—The annual meeting of the Texas State Medical Association will be held in Fort Worth, April 24, 25 and 26. Dr. William R. Thompson is chairman of the committee of arrangements; Dr. Bacon Sanders of the subcommittee on finance; Dr. Frank D. Thompson of the subcommittee on transportation; Dr. John R. Fraser of the subcommittee on reception, and Dr. Frank D. Boyd of the committee on entertainment and place of meeting.

Personal.—Dr. J. H. Florence, quarantine officer at Brownsville, is acting as state health officer during Dr. Tabor's stay in Europe.—Dr. John W. Burns, Cuero, is visiting in New York.—Dr. William J. Matthews, Austin, is seriously ill from overwork.—Dr. Thomas W. Wiley, McKinney, has been appointed chief surgeon of the Texas, New Mexico & Pacific Railway.—Dr. Charles W. Trueheart, city health officer of Galveston, is reported to be critically ill.—Dr. William Myers, Seguin, was thrown from his buggy in a runaway accident and his hip and clavicle broken.

Medical Society Meetings. The Tri-State Medical Society of Arkansas, Texas and Louisiana held its second annual meeting in Texarkana, Ark., December 6. The following officers were elected: Dr. Oscar Dowling, Shreveport, La., president;

Drs. Charles M. Rosser, Dallas, Texas; M. G. Thompson, Hot Springs, Ark., and Luther Longino, Minden, La., vice-presidents; and Dr. Robert H. T. Mann, Texarkana, Ark., secretary. —The South Texas District Medical Association held its annual meeting December 13 and 14, at which the following officers were elected: Dr. D. Stuart Wier, Beaumont, president; Dr. Perry G. Swearingen, Center, censor; Dr. Jordan, Liberty, vice-president; and Dr. Albert A. Nelson, Nacogdoches, secretary and treasurer. Houston was selected as the next place of meeting. —The Seventh Councilor District Medical Society held its annual meeting in Austin, December 21, at which the following officers were elected: Dr. Joseph A. Holloway, Round Rock, president; Dr. Joseph Gilbert, Austin, secretary; and Drs. Andrew J. Sibley, Creedmore; E. Matt Thomas, Georgetown; James C. Anderson, Granger; Homer B. Hill, Austin, and S. E. Hudson, Austin, censors. —At a meeting held February 16, the Negro Medical Association of Fort Worth was organized with the following officers: Dr. Peter R. Robinson, president; Dr. W. T. Hughes, treasurer; Dr. J. M. Mosely, reporter, and Dr. Franklin W. Adams, secretary.

GENERAL.

A Moral Victory for the Ladies' Home Journal.—A jury of the Supreme Court, at Buffalo, N. Y., recently awarded the World's Dispensary Medical Association, proprietors of a "patent medicine" known as Dr. Pierce's Golden Medical Discovery, \$16,000 damages in a suit for libel against the Curtis Publishing Company, publishers of the *Ladies' Home Journal*. The libel consisted in a statement that this particular medicine contained opium, digitalis and alcohol. The suit was originally brought for \$200,000 damages and the award was so small that the plaintiff immediately made a motion for a new trial on the ground of inadequate damages.

Health Report of the Philippines for October.—The health report of the Board of Health for the Philippine Islands for October states that during the month 842 births were recorded, of which 452 were males and 390 females. There were 904 deaths, or an average of 29 deaths per diem. This is a lower death rate than for the two preceding months. During the month there were 31 cases of cholera, with 29 deaths. The infant mortality, especially among children included in the groups of "under 30 days," and "between 30 days and one year," reached 468. This was 62 more than during the preceding month.

FOREIGN.

Cholera Declining in Russia.—It is reported, by way of Berlin, that the Russian cholera commission has declared the Vistula district, the districts of Wolhynia and Kurland, and the city of Lomza free from cholera.

Research on Etiology of Syphilis.—A Berlin lawyer named Salomonsohn recently founded an endowment to aid scientific research. The first grant (\$400) from the endowment has been given to J. Siegel, the discoverer of the *Cryptorhynchus luis*, to enable him to continue his studies on the etiology of syphilis.

Wealthy Physician Labors Among Poor.—Duke Carl Theodore of Bavaria is a well-known physician, having long made ophthalmology his specialty. He recently performed his five-thousandth cataract operation, assisted by Dr. Zenker, and by his wife, who was the Princess Maria of Portugal. She has always taken an interest in his work and frequently assists him. It is said that he never accepts a fee from any patient, devoting his services to the poor. He lives in Munich and has made many endowments for hospitals and other charitable purposes.

Smallpox in Mexico.—Consul Lespinasse reports from Tuxpan, February 7, that an epidemic of smallpox prevails in that vicinity, but that other settlements and municipalities included in the county are exempt from the disease. Since November 29, the date on which the first case of the epidemic occurred, 60 cases have been recorded. Of these patients 26 have recovered, 12 have died, and 22, most of whom will recover, are still under treatment. The measures adopted to check the course of the epidemic consist of isolation of the sick, necessary aid to the sufferers, and prompt disinfection of the houses in which smallpox patients have been treated.

Board and Lodgings at Lisbon International Medical Congress.—The executive committee sends word to THE JOURNAL that a large number of rooms, with one or more beds, have been secured for the accommodation of the members of the congress. The rates will be from 6 to 10 francs per bed (about \$1.50 to \$2.50). Rooms with board can also be secured for 15 francs, or \$3 a day for each person. A restaurant will be run in connection with the congress, and meals can also

be obtained at the restaurants and hotels of the city. The rooms will be assigned in turn as the demands are received. Mr. Manoel José da Silva, Palácio Foz, Praça dos Restauradores, Lisbon, has charge of this service. The French, Spanish, Portuguese and Italian railroads allow a reduction of 50 per cent, and a change of route going and coming, on condition that the trip is by rail each way. See page 597 for further particulars; see also Correspondence Department in this issue.

LONDON LETTER.

The Amalgamation of the London Medical Societies.

Considerable progress has been made in the scheme for the amalgamation of the numerous London medical societies which has been previously described in THE JOURNAL. At a meeting of the representatives in December an organizing committee was appointed to draw up a detailed scheme. In order to ascertain the amount of financial support likely to be received a circular was issued to over 5,000 doctors, asking for an immediate reply to certain questions as to the probability of their joining the new society as fellows or members. A fellow will pay a subscription of \$15 a year, which will give him the right to attend discussions in all sections, to use the general library, and to receive the proceedings and transactions of the society. A member of only a section will pay \$5 a year and will have the right to take part in the proceedings of the section, to receive its publications, and to use the general reading room. Such a member will be entitled to join other sections on payment of \$2.50 for each additional section, and to obtain the use of the general library for a further subscription of \$5. Every member of a society joining the amalgamation who desires to become a member of the corresponding section or a fellow of the new society will be able to do so without election. It is proposed that those elected subsequently shall pay an entrance fee, and that only the members of a section shall have the power to vote on matters of the section.

The Rebuilding of the London Hospital.

Within the last few weeks the reconstruction of the largest general hospital in England has been completed at a cost of over \$2,150,000. The hospital has been practically rebuilt and now presents a remarkable example of perfection in so far as a well-built structure, part of which dates from 1752, can be compared with new buildings erected regardless of the value of land. Of the sum expended at least \$1,650,000 has been subscribed by the public for the purpose. The remaining \$500,000 has been taken from the invested funds of the institution. The state of the hospital eight years ago amounted to a scandal. There were 780 beds and but one operating theater. The pressure on this single theater was such that the patients had to wait their turn in a fashion which amounted to absolute cruelty. Now there are eight operating theaters, five of which are in daily use, the other three being required not less than four days a week. There are now 937 beds in the hospital. Formerly the out-patient department was totally inadequate to deal with the 161,000 individual out-patients who there sought relief—a number which has now increased to 206,000. There were no proper seclusion and isolation wards. The ophthalmic cases were accommodated in a damp basement below the ground level. The arrangements for children were such that the constant outbreaks of infectious disease paralyzed the whole work.

The London School of Clinical Medicine.

The organization of the old Seamen's Hospital at Greenwich as a postgraduate school, which promises to be one of the most important in this country, has recently been described in THE JOURNAL. At a meeting of one of the branches of the British Medical Association, held at the hospital, special attention was directed to the advantages offered by it as a postgraduate school. Sir Dyce Duckworth, who presided, said that the hospital had done excellent work in the past, but during the last few months the staff had been materially increased and included members well known to the medical world at large as eminent in their several departments. He said that no institution so well equipped for the purpose had been organized in London, and was a great advance in the direction of supplying a want that had long been felt. He said that medical men from various parts of the world go to England and, not finding what existed in Germany and France, turned their backs on London and betook themselves to other countries. The hospital provided accommodation chiefly for sailors, and in connection with the School of Tropical Medicine, of which it formed part, it provided for observation splendid examples of tropical diseases—dysentery and beriberi. Thus an excellent field is provided for officers of the navy and army and for those who are fitting themselves for colonial practice.

Disease in the Port of London.

During the past two months 6,207 vessels entered the port of London and were inspected by the medical staff. Of these, 5,304 were British. Thirty-eight cases of infectious disease were dealt with, viz.: Chickenpox, 13; typhoid fever, 13; measles, 6; erysipelas, 1; scarlet fever, 1, and Malta fever, 1. Three cases of beriberi have been reported. A large quantity of unsound food was seized and destroyed at the docks and warehouses, particularly some extensive importations of beef and mutton from the River Plate and Buenos Ayres. The extermination of rats still continues. The total number destroyed so far amounts to 389,543.

Medical Legislation

The Pure Food Bill.

The following is the text of the Pure Food Bill as amended and now before the House of Representatives:

"An Act for preventing the adulteration or misbranding of foods or drugs, and for regulating traffic therein, and for other purposes."

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

"That the introduction into any state or territory or the District of Columbia from any other state or territory or the District of Columbia, or from any foreign country, or shipment to any foreign country of any article of food or drugs which is adulterated or misbranded, within the meaning of this act, is hereby prohibited; and any person who shall ship or deliver for shipment from any state or territory or the District of Columbia to any other state or territory or the District of Columbia, or to a foreign country, or who shall receive in any state or territory or the District of Columbia from any other state or territory or the District of Columbia, or foreign country, or who, having received, shall deliver, in original unbroken packages, for pay or otherwise, or offer to deliver to any other person, any such article so adulterated or misbranded within the meaning of this act, or any person who shall sell or offer for sale in the District of Columbia or the territories of the United States any such adulterated or misbranded foods or drugs, or export or offer to export the same to any foreign country, shall be guilty of a misdemeanor, and for such offense be fined not exceeding \$200 for the first offense, and on conviction for each subsequent offense not exceeding \$300 or be imprisoned not exceeding one year, or both, in the discretion of the court: Provided, however, that no person shall be liable to the penalty of imprisonment as provided herein unless he knowingly committed the offense charged: Provided further, that no article shall be deemed misbranded or adulterated within the provisions of this act when intended for export to any foreign country and prepared or packed according to the specifications or directions of the foreign purchaser when no substance is used in the preparation or packing thereof in conflict with the laws of the foreign country to which said article is intended to be shipped; but if said article shall be in fact sold or offered for sale for domestic use or consumption, then this proviso shall not exempt said article from the operation of all the other provisions of this act."

TO ESTABLISH METHODS OF PROCEDURE.

"Sec. 2. That the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor shall make uniform rules and regulations for carrying out the provisions of this act, including the collection and examination of specimens of foods and drugs manufactured or offered for sale in the District of Columbia, or in any territory of the United States, or which shall be offered for sale in unbroken packages in any state other than that in which they shall have been respectively manufactured or produced, or which shall be received from any foreign country, or intended for shipment to any foreign country, or which may be submitted for examination by the chief health, food, or drug officer of any state, territory, or the District of Columbia, or at any domestic or foreign port through which such product is offered for interstate commerce, or for export or import between the United States and any foreign port or country."

METHODS OF EXAMINATIONS.

"Sec. 3. That the examinations of specimens of foods and drugs shall be made in the Bureau of Chemistry of the Department of Agriculture, or under the direction and super-

vision of such bureau, for the purpose of determining from such examinations whether such articles are adulterated or misbranded within the meaning of this act; and if it shall appear from any such examination that any of such specimens is adulterated or misbranded within the meaning of this act, the Secretary of Agriculture shall cause notice thereof to be given to the party from whom such sample was obtained. Any party so notified shall be given an opportunity to be heard, under such rules and regulations as may be prescribed as aforesaid, and if it appears that any of the provisions of this act have been violated by such party, then the Secretary of Agriculture shall at once certify the facts to the proper United States district attorney, with a copy of the results of the analysis or the examination of such article, duly authenticated by the analyst or officer making such examination, under the oath of such officer. After judgment of the court notice shall be given by publication in such manner as may be prescribed by the rules and regulations aforesaid."

PROSECUTIONS.

"Sec. 4. That it shall be the duty of each district attorney to whom the Secretary of Agriculture shall report any violation of this act, or to whom any health or food or drug officer or agent of any state, territory, or the District of Columbia, shall present satisfactory evidence of any such violation, to cause appropriate proceedings to be commenced and prosecuted in the proper courts of the United States, without delay, for the enforcement of the penalties as in such case herein provided."

DEFINITION OF "DRUG" AND "FOOD".

"Sec. 5. That the term 'drug,' as used in this act, shall include all medicines and preparations recognized in the United States Pharmacopoeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals. The term 'food,' as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or other animals, whether simple, mixed, or compound."

DEFINITION OF "ADULTERATION".

"Sec. 6. That for the purposes of this act an article shall be deemed to be adulterated:

"In case of drugs:

"First.—If, when a drug is sold under the standard recognized in the United States Pharmacopoeia or National Formulary, it differs from the standard of strength, quality, or purity, as determined by the test laid down in the United States Pharmacopoeia or National Formulary official at the time of the investigation."

"Second.—If its strength or purity differ from any other professed standard or quality under which it is sold."

"In the case of confectionery:

"If it contain terra alba, barytes, talc, chrome yellow, or other mineral substance or poisonous color or flavor, or other ingredient deleterious or detrimental to health."

"In the case of food:

"First.—If any substance has been mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength."

"Second.—If any substance has been substituted wholly or in part for the article."

"Third.—If any valuable constituent of the article has been wholly or in part abstracted."

"Fourth.—If it be mixed, colored, powdered, coated, or stained in a manner whereby damage or inferiority is concealed."

"Fifth.—If it contain any added poisonous or other added deleterious ingredient which may render such article injurious to health: Provided, that when in the preparation of food products for shipment they are preserved by an external application applied in such manner that the preservative is necessarily removed mechanically, or by maceration in water, or otherwise, the provisions of this act shall be construed as applying only when said products are ready for consumption."

"Sixth.—If it consists in whole or in part of a filthy, decomposed, or putrid animal or vegetable substance, or any portion of an animal unfit for food, whether manufactured or not, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter."

DEFINITION OF "MISBRANDING".

"Sec. 7. That the term 'misbranded,' as used herein, shall apply to all drugs, or articles of food, or articles which enter into the composition of food, the package or label of which

shall bear any statement regarding the ingredients or substances contained in such article, which statement shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the state, territory, or country in which it is manufactured or produced.

"That for the purposes of this act an article shall also be deemed to be misbranded:

"In case of drugs:

"*First*.—If it be an imitation of or offered for sale under the name of another article.

"*Second*.—If the contents of the original package shall have been removed, in whole or in part, and other contents shall have been placed in such package, or if it fail to bear a statement on the label of the quantity or proportion of any alcohol therein, or of any opium, cocaine, or other poisonous substance which may be contained therein.

"In the case of food:

"*First*.—If it be an imitation of or offered for sale under the distinctive name of another article.

"*Second*.—If it be labeled or branded so as to deceive or mislead the purchaser, or purport to be a foreign product when not so.

"*Third*.—If in package form, the quantity of the contents of the package be not plainly and correctly stated in terms of weight or measure, on the outside of the package.

"*Fourth*.—If the package containing it or its label shall bear any statement, design, or device regarding the ingredients or the substances contained therein, which statement, design, or device shall be false or misleading in any particular: Provided, that an article of food which does not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated or misbranded in the following cases:

"*First*.—In case of mixtures or compounds which may be now or from time to time hereafter known as articles of food, under their own distinctive names, and not an imitation of or offered for sale under the distinctive name of another article, if the name be accompanied on the same label or brand with a statement of the place where said article has been manufactured or produced.

"*Second*.—In the case of articles labeled, branded, or tagged so as to plainly indicate that they are compounds, imitations, or blends: Provided, that the term blend as used herein shall be construed to mean a mixture of like substances, not excluding harmless coloring or flavoring ingredients: And provided further, that nothing in this act shall be construed as requiring or compelling proprietors or manufacturers of proprietary foods which contain no unwholesome added ingredient to disclose their trade formulas, except in so far as the provisions of this act may require to secure freedom from adulteration or misbranding."

PROTECTION OF THE RETAILER WHO HAS GUARANTEES.

"*Sec. 8.* That no dealer shall be convicted under the provisions of this act when he is able to prove a guaranty of conformity with the provisions of this act in form approved by the rules and regulations herein provided for, signed by the manufacturer or the party or parties from whom he purchased said articles: Provided, that said guarantor resides within the United States. Said guaranty shall contain the full name and address of the guarantor making the sale to the dealer, and said guarantor shall be amenable to the prosecutions, fines, and other penalties which would otherwise attach in due course to the dealer under the provisions of this act."

COMMISSION OF EXPERTS.

"*Sec. 9.* That it shall be the duty of the Secretary of Agriculture to fix standards of food products when advisable for the guidance of the officials charged with the administration of food laws and for the information of the courts, and to determine the wholesomeness or unwholesomeness of preservatives and other substances which are or may be added to foods; and to aid him in reaching just decisions in such matters he is authorized to call on the committee on food standards of the Association of Official Agricultural Chemists and the committee of standards of the Association of State Dairy and Food Departments, and such other experts as he may deem necessary."

"And on request made to the Secretary of Agriculture prior to reaching any decision as provided for in this section, by any manufacturer or other person interested, asking for the appointment of a board to determine the wholesomeness or unwholesomeness of any preservative or other substance which is or may be added to foods, and concerning the use of which the person making the request has an interest, it shall be the duty of the Secretary of Agriculture to appoint a board of distinguished experts, which board shall consist of five members, one of

whom shall be an expert toxicologist, one an expert physiologic chemist, one an expert bacteriologist, one an expert pathologist, and one an expert pharmacologist, which board shall meet at the city of Washington, District of Columbia, or elsewhere, at the call of the Secretary of Agriculture, and pass on such question after proper notice and hearing granted to the person making such request. The compensation of the members of such board shall be fixed by the Secretary of Agriculture."

HOW SAMPLES MAY BE PROCURED.

"*Sec. 10.* That every person who manufactures or produces for shipment and delivers for transportation within the District of Columbia or any territory, or who manufactures or produces for shipment or delivers for transportation from any state, territory, or the District of Columbia, to any other state, territory, or the District of Columbia, or to any foreign country, any drug or article of food, and every person who exposes for sale or delivers to a purchaser in the District of Columbia or any territory any drug or article of food manufactured or produced within said District of Columbia or any territory, or who exposes for sale or delivers for shipment any drug or article of food received from a state, territory, or the District of Columbia other than the state, territory, or the District of Columbia in which he exposes for sale or delivers such drug or article of food, or from any foreign country, shall furnish within business hours and on tender and full payment of the selling price a sample of such drug or article of food to any person duly authorized by the rules and regulations herein provided for to receive the same, and who shall apply to such manufacturer, producer, or vendor, or person delivering to a purchaser, such drug or article of food, for such sample for such use, in sufficient quantity for the analysis of any such drug or article of food in his possession.

"*Sec. 11.* That any manufacturer, producer, or dealer who refuses to comply, on demand, with the requirements of section ten of this act shall be guilty of a misdemeanor, and on conviction shall be fined not exceeding \$100, or imprisoned not exceeding 100 days, or both. And any person found guilty of manufacturing or offering for sale, or selling, an adulterated, or misbranded article of food or drug in violation of the provisions of this act may, in the discretion of the court, be adjudged to pay, in addition to the penalties hereinbefore provided for, all the necessary costs and expenses incurred in inspecting and analyzing such adulterated articles which said person may have been found guilty of manufacturing, selling, or offering for sale."

LIMITED TO INTERSTATE COMMERCE.

"*Sec. 12.* That this act shall not be construed to interfere with commerce wholly internal in any state, nor with the exercise of their police powers by the several states; but foods and drugs fully complying with all the provisions of this act shall not be interfered with by the authorities of the several states when transported from one state to another so long as they remain in original unbroken packages, except as may be otherwise defined by law or provided by statutes of the United States."

SEIZURE OF GOODS.

"*Sec. 13.* That any article of food or drug that is adulterated or misbranded within the meaning of this act, and is transported or being transported from one state to another for sale, or if it be sold or offered for sale in the District of Columbia or any territory of the United States, or if it be imported from a foreign country for sale, or if intended for export to a foreign country, shall be liable to be proceeded against in any district court of the United States, within the district where the same is found, and seized by a process of libel for condemnation. And if such article is condemned as being adulterated or misbranded, within the meaning of this act, the same shall be disposed of as the said court may direct, and the proceeds thereof, if sold, less the legal costs and charges, shall be paid into the treasury of the United States, but such goods shall not be sold in any state contrary to the laws of that state. The proceedings of such libel cases shall conform as near as may be to the proceedings in admiralty, except that either party may demand trial by jury of any issue of fact joined in such case; and all such proceedings shall be at the suit of and in the name of the United States."

TO EXAMINE GOODS FOR EXPORT.

"*Sec. 14.* That the Secretary of Agriculture is authorized to investigate the character and extent of the adulteration of foods and drugs, and whenever he has reason to believe that articles are being imported from foreign countries which by reason of such adulteration are dangerous to the health of the

people of the United States, or are of kinds which are forbidden entry into or forbidden to be sold or restricted in sale in the countries in which they are made or from which they are exported, or which shall be falsely labeled in any respect, either by the omission of the name of any added ingredient or otherwise, or in regard to the place of manufacture, or the contents of the package, shall make a request on the Secretary of the Treasury for samples from original packages of such articles for inspection and analysis; and the Secretary of the Treasury is hereby authorized to open such original packages and deliver specimens to the Secretary of Agriculture for the purpose mentioned, giving due notice to the owner or consignee of such articles, who may appear before the Secretary of Agriculture and have the right to introduce testimony; and the Secretary of the Treasury shall refuse delivery to the consignee of any of such goods which the Secretary of Agriculture reports to him have been inspected and analyzed and found to be any of the kinds mentioned in this section: Provided, that the Secretary of the Treasury may deliver to the consignee such goods, pending examination and decision in the matter, on execution of a penal bond of the full invoice value of such goods, together with the duty thereon, and on refusal to return such goods for any cause to the custody of the Secretary of the Treasury, when demanded, for the purpose or excluding them from the country, or for other purposes, said consignee shall forfeit the full amount covered by the bond.

"Sec. 15. That the term 'territory' as used in this act shall include the insular possessions of the United States.

"Sec. 16. That this act shall be in force and effect from and after its passage; Provided, however, that no penalties herein named shall be imposed until after the expiration of one year from the passage of the act."

To Investigate the Proprietary Association.

The following resolution, introduced into the House of Representatives March 5, 1906, by Mr. Gillespie, was referred to the committee on Judiciary and ordered to be printed. The possibilities involved in an investigation of the bodies mentioned are interesting.

WHEREAS, It is alleged that John W. Jennings, a citizen of the United States, engaged in the sale of drugs, chemicals, patent medicines and proprietary articles at wholesale and retail at number six hundred and thirty-two and thirty-three West Street, and number eleven hundred and thirty-nine Eighteenth Street, in the city of Washington, District of Columbia, is being conspired and discriminated against by certain combinations, in violation of the Act of Congress of July second, eighteen hundred and ninety, entitled "An Act to protect trade and commerce from unlawful restraints and monopolies," namely: The Proprietary Association of America, an unincorporated association composed of upward of ninety per centum of all the manufacturers and proprietors of patent medicines, chemicals, and proprietary articles within the United States, whose members reside and do business in the several states of the United States; The National Wholesale-Druggists' Association, an unincorporated association composed of upward of ninety per centum of all the wholesale druggists of the United States, whose members are the distributing agents for manufacturers and proprietors of patent medicines, drugs, chemicals and proprietary articles, purchasing the same from manufacturers in the several states of the United States and in foreign markets, and selling and supplying the same to retail druggists throughout the United States; The National Association of Retail Druggists, briefly known as the N. A. R. D., an unincorporated association having a membership composed of local associations of retail druggists and other kindred associations; and

WHEREAS, It is alleged that the aforesaid Jennings, by reason of his non-affiliation with the District of Columbia Retail Druggists' Association, the local branch of the aforesaid N. A. R. D., has been for several years past and is now blacklisted, and thereby prevented from buying in open market any drugs, patent medicines, chemicals and proprietary articles manufactured or controlled by the members of the aforesaid associations; and

WHEREAS, It is alleged that the said discrimination and blacklisting have resulted in heavy financial loss to the aforesaid Jennings and threaten the ruin of his business; and

WHEREAS, It is alleged that the aforesaid Jennings, on Feb. 15, 1905, filed before the Department of Justice a petition setting forth the aforesaid grievances; and

WHEREAS, It is alleged that up to the present time no action has been taken by the Department of Justice on the aforesaid petition. Therefore be it

Resolved, That the Attorney-General of the United States be, and he is hereby, requested, if not incompatible with the public interest, to report to the House of Representatives at his earliest convenience for its guidance, all the information within the knowledge of his department which shows or tends to show that there exists now, or within the past twelve months has existed, a combination or arrangement between the wholesale and retail druggists, manufacturers of patent medicines, drugs, chemicals and proprietary articles, whereby a druggist not a member of one of the aforesaid associations has been or is now being discriminated against in violation of the Act of Congress of July 2, 1890, entitled "An Act to protect trade and commerce from unlawful restraints and monopolies," or acts amendatory thereof; also what steps have been taken by the Department of Justice looking to the prosecution of the petition of the aforesaid Jennings, filed before the department on February 15, 1905, as herein above set forth.

New Jersey Committee on Legislation.

WILLIAMSTOWN, N. J., March 2, 1906

To the Editor:—I am inclosing a list of the National Auxiliary Legislative Committee of the state of New Jersey. This committee has been named at the suggestion of Dr. Reed, chairman of the National Committee on Legislation, so that each state should be thoroughly organized, and the National Committee on Legislation should be able to reach every county in each state.

We are trying to take up the work and to do everything in our power to assist the National Committee on Legislation, and at the same time to look after matters in our own state. We have a State Auxiliary Legislative Committee, which is composed of one member from each county medical society, and we are getting in close touch with the profession's demands throughout the state.

The "patent-medicine" bill has been introduced in our legislature and we are going to do everything that is possible to pass the bill.

We have taken up all the matters as suggested at the conference of the National Legislative Committee, with our senator and congressmen, and in most cases have received responses from them that they are ready to co-operate with us on all matters which we discussed at the meeting of the National Legislative Council.

New Jersey is, I think you will find, ever ready to do her part and to assist in any way possible for the advancement of the medical profession on sanitary matters.

L. M. HALSEY, Chairman.

LIST OF THE NATIONAL AUXILIARY, LEGISLATIVE COMMITTEE OF NEW JERSEY.

Atlantic County	Dr. Edgar Darnell	Atlantic City
Bergen County	Dr. D. A. Currie	Englewood
Burlington County	Dr. W. P. Melcher	Mt. Holly
Cumberland County	Dr. J. H. Moore	Bridgeton
Camden County	Dr. Daniel Struck	Camden
Cape May County	Dr. M. P. Lummis	Mt. Holly Beach
Essex County	Dr. Ralph D. Hunt	29 Harrison St., E. Orange
Glocester County	Dr. Geo. C. Laws	Paulsboro
Hudson County	Dr. Samuel A. Jellison	Hoboken
Mercer County	Dr. Elmer Jarvis	Trenton
Middlesex County	Dr. David C. English	New Brunswick
Monmouth County	Dr. D. McLean Forman	Freehold
Morris County	Dr. H. W. Kier	Wharton
Ocean County	Drs. L. C. Linday and W. G. Schaffer	Lakewood
Passaic County	Dr. John L. Leal	Paterson
Salem County	Dr. W. H. Carpenter	Salem
Somerset County	Dr. John P. Hecht	Somerville
Sussex County	Dr. M. D. Hughes	Laxton
Union County	Dr. N. L. Wilson	Elizabeth
Warren County	Dr. John C. Johnson	Bladestown

Correspondence

Interstate Reciprocity.

DETROIT, March 10, 1906.

To the Editor:—Dr. George W. Webster states in reply to my letter in THE JOURNAL, March 3, 1906, in which I interpret his proposed plan of action to make practical his basis of reciprocity as in conflict with the authority and purposes of state medical boards, and in which also I suggest that his committee could be effective from a standpoint of education working in harmony with the Association of American Medical Colleges—as follows:

"I regret very much that Dr. Harrison seems to have utterly failed to grasp the fundamental ideas which I tried to convey, namely: that the American Medical Association is desirous of assisting the examining boards, and that the plan proposed is not simply a scheme of reciprocity but a proposed plan of education, which, if successfully carried out, will serve as a rational foundation on which reciprocity will naturally rest."

A careful review of his article failed to find even a direct or indirect reference to the medical boards as a factor in his plan to make practical the accepted basis of reciprocity, but I do find the unequivocal statements that the basis of reciprocity can only be made effective through the Council on Education of the American Medical Association. As corroborative evi-

dence of his intent may be mentioned his ignoring completely the existence of the American Confederation, which is in complete and effective possession of the field which he proposed to operate and improve. If Dr. Webster were simply desirous of assisting the medical boards and had proposed a plan of education only, he should not have ignored the two most important factors—medical boards, represented by the American Confederation, and the medical colleges, represented in a large degree by the Association of American Medical Colleges. I am pleased, however, to accept without further reservation, his statement that the Council on Medical Education proposes to limit its endeavors to the educational phase of the question.

In reference to that portion of Dr. Webster's reply which deals principally with himself and his personal achievements and services to the profession and to the causes of educational reciprocity, I have to say that I fully appreciate and gladly credit Dr. Webster's great ability as well as his activity in all matters pertaining to the good of the profession, and the objects it has in view, but I am not prepared to go the length of supporting him in his contention that either he or the National Confederation are the authors of the present method of standard adopted by the Association of American Medical Colleges, or by the American Confederation. He states that in 1903, and again in 1904, the National Confederation of State Medical and Licensing Boards adopted his standard curriculum, and that this curriculum, which assigned a certain number of hours in the course to each subject, was the first curriculum to be adopted by any organization, and that it was subsequently adopted by the Association of American Medical Colleges and the American Confederation without any important modifications. Is his statement based on facts? As early as July, 1900, the Michigan State Medical Board published and enforced an itemized medical standard, divided into lectures, teaching, and laboratory work, and in June, 1902, published a further itemized standard of both preliminary and medical education, the latter divided into lectures, laboratory, and clinics, while Dr. Webster's standard of three years later contains simply the total number of hours for each subject, without division into lectures, laboratory, and clinics, and therefore was a much less developed method, and possessed nothing of the Michigan original, except in its crudeness.

In 1904 the American Confederation adopted the Michigan method of standard, both of preliminary and medical education, but postponed the final adoption of the detail until subsequent to the 1905 meeting of the Association of American Medical Colleges, in order that the standards of the Confederation of Boards and the Association of Colleges should harmonize.

As a member of, and secretary of the confederation committee in charge of the standards, I can state that Dr. Webster's curriculum was not considered by the committee, or even known to have an existence. The committee of the Association of American Medical Colleges, of which Dr. Kober was chairman, in its printed report, which was adopted, presented in parallel columns the proposed standard of 4,000 hours, divided into lectures, laboratory, and clinics (exactly in harmony with the Michigan method) and the Michigan standard of 4,000 hours. With some slight variation in the detail of hours per subject these standards were exactly uniform.

Looking up the last two or three years' official report of the Association of Medical Colleges I find frequent reference to the Michigan standard and method, but no reference to Dr. Webster's curriculum, or the National Confederation. If those interested could see in print, for comparison, the curriculum of the National Confederation of 1903 and 1904, which Dr. Webster claims as his offspring, and the standard curriculum of the Association of American Medical Colleges, and also the Michigan curricula of each year since 1900, which have been incorporated in her application forms since 1902, the fallacy of Dr. Webster's claim of originality would be fully appreciated. Especially so in connection with his statement made at the Portland session last years, as follows:

"Dr. G. W. Webster of Illinois said that while there had been much talk of raising the standard no real standard has as yet been established."

As an additional evidence of inconsistency in Dr. Webster's claim might be mentioned the fact that the state board of

which he is president, and its most influential member, has as yet failed to adopt the method of standard which he states was originated by him in 1903, and which was actually in practical use in Michigan three years prior to this date.

In connection with the above I also desire to refer briefly to the published letter of commendation received by Dr. Webster from Dr. George M. Kober, in which it would appear that the latter indorses his claim that he alone of all others deserves credit for the standard curriculum, which at a later date Dr. Webster denies exists.

I am pleased to note that Dr. Webster, like the rest of us, is subject to the human weakness of appreciating credit for personal good works. I also received an almost similar letter from Dr. Kober, with this difference, perhaps—the one letter was based on the belief and kindly appreciation for services attempted; the other on fact. While such letters are usual, proper, and often helpful, it was never contemplated by their author that they should be used in the manner Dr. Webster used the one received by him. They should never be taken too seriously or literally by the fortunate recipients, besides, such letters are not material to the cause which Dr. Webster and myself have at heart, and the methods of obtaining which we are now agreed on. Indeed, the discussion seems to have been diverted from the original subject of reciprocity to one of personal claims and credit, for which I do not hold myself responsible.

B. D. HARRISON.

Lisbon and Its People.—Some Interesting Facts for Those Attending the International Congress.

BALTIMORE, March 1, 1906.

To the Editor:—Having received numerous letters of inquiry regarding Lisbon and its people I take this opportunity to give a few facts to those who are to attend the congress. Being well acquainted with the people of Portugal, I regret that I can not do them greater justice, but material for a medical journal has its limits.

Contrary to the general opinion, Portugal differs sensibly from Spain in its social, intellectual and moral life. Ethnographically the inhabitants of the two countries are the same race, but apart from this there is a great difference between the two races.

The primitive traits of the Portuguese have been changed by long series of mixtures between the original inhabitants and foreigners. This amalgam, which was produced during and directly after Portugal's great geographical discoveries, has brought about a physiognomic difference which is noticeable the moment the traveler reaches the Spanish-Portuguese frontier.

Throughout Portugal the national type remains the same, but the mode of life, costumes, habits and morals vary in different parts of the country. These differences are distinct; for instance, the Minhotos are cultivators of the soil, intelligent and serious in their work, but on fête days they are gay, joyous and great admirers of pretty women and jewelry. The grape pickers and winggrowers of Douro, the inhabitants of the Beira, sometimes shepherds, sometimes fishermen, are hard workers, but their tasks finished they enjoy themselves in sports and drinking. The mountaineers are a strong, virile race with meditative manners and austere morals.

One feature, however, is characteristic of all Portugal. This is the beautiful, brilliant and desirous eyes of the women. The latter are handsome, have blooming complexions and in all anatomic traits accentuate their sex. Short in stature, they are well proportioned, esthetic in carriage, opulent in physiologic functions, and have pretty, tiny feet and hands. Their shining and jetty hair makes a striking contrast to their milk-white foreheads, rosy cheeks and pink lips.

Intellectually and morally the Portuguese offer an interesting melange of good qualities and bad faults. They are a lovable race when you know them well. They are invariably kind to the poor, gentle to their beasts, and open-hearted to the properly introduced foreigner.

It is announced that the members of the congress will be invited to witness a bullfight in Lisbon. I advise everyone to go. You may with perfect security to any sensitiveness take your wives and daughters. A Portuguese bullfight differs

from a Spanish bullfight as much as a game of bean-bag differs from a college football game. There is no bloodshed, nothing repugnant, but plenty of hilarity, and frequently great athletic ability is displayed by men, horses and bulls. On the short horns of the latter are placed large rubber balls. Sometimes the horse manages to kick the bull in the ribs, when he utters a roar of indignation and returns the insult by butting the horse with his rubber buffers. This pleases the risible centers of the happy Portuguese and the bullfight is over.

There is much that pertains to the Orient in the customs and architecture of Portugal, and the many social laws are undoubtedly only modified conditions that existed when the Moors ruled the peninsula.

The higher classes in Lisbon and Oporto well appreciate the value of educating their daughters, yet conditions are such that the girls must be confined to conventual supervision. In order to maintain this oversight on the young women, yet have them free to enjoy the learning of other countries, they are taught by English and Irish women. The great convent schools of Bom Sucesso and Salesias, where the girls of the best society are sent, are controlled exclusively by English and Irish sisters.

This naturally brings me to what I shall have to confine myself in this article—educational matters—though I feel no adequate justice can be done to the charming Portuguese people by neglecting to tell of their home life, or of the struggle educated people, including the king, are making for freedom in religious thought.

There exists in Portugal only one educational institution bearing the honor and title of a university. This was founded in Lisbon in 1288 and transferred in 1307 to Coimbra (pronounce, but do not indite, *Quimbré*). A bull of Gregory XI was issued October, 1376, which authorized the university to give degrees in letters and theology. In 1377 the university was again transferred to Lisbon, but 200 years later removed to its former home, Coimbra, where it has remained. It has been the battleground for science and religion through many a century. In 1836 came the great movement of the reformers and then were established under the direct control of the government the departments of medicine, law and the arts. Gradually it became a school of modern ideas, and has kept well up in the progress of nations.

The university is composed of five faculties: medicine, law, theology, mathematics and physics. This last faculty has under its control all instruction in the natural sciences and attached to it are excellent botanical and zoological gardens. The chairs of Greek and Hebrew are under the charge of the theological faculty. The university buildings are massive, handsome and unique in their architectural designs. They should be well studied, for nowhere throughout the world will the traveler find their equal. The library is large, its decorations are rich and immensely valuable, and combine all the Oriental splendor of the Alhambra with the utility of the libraries in St. Mark's, Venice.

The course of instruction at the great Portugal university is essentially modern in that it is free from church interference and generously supported by the state. The professors and those foreigners who are invited to talk to the students have the freedom of the air to say what they think. (This in some respects differs from a few of our universities.)

The professors of Coimbra, all Portuguese, are divided into fifty-three lecturers (*lentes*) and twenty-two associate lecturers (*substitutos*). The members of the different faculties are designated by their capes and hats, as follows: Medicine, yellow, 18 members; law, red, 21 members; mathematics, blue, 13 members; philosophy, blue and white, 11 members, and theology, white, 9. On all official occasions and at examinations the professors are dressed in their distinctive robes and hats. The students are obliged to wear a uniform of black cloth, composed of short breeches, cape and black hat, of a disgraceful shape and size. For this latter reason the students go bareheaded except on official occasions.

The last statistics show that there are 1,180 students in all departments, divided as follows: Law, 510; mathematics, 130; medicine (and pharmacy), 140; and in the natural sciences,

360, while it will undoubtedly surprise many readers to learn that in the department of theology there are only 40 students.

The course is five years, and the charge for instruction about \$30 a year, except in medicine, where it is somewhat greater. The minimum age is 16 years, but the average age of the students is about 19. Women are rarely seen at the university, the woman of cannibal tendency not yet having arrived at Portugal. One lone woman of mixed inheritance received a degree of philosophy in 1894. She has disappeared. There are few foreigners at the university, unless we class the Brazilians as such. These latter of Portuguese blood, attend in large numbers.

In Oporto there is a school of medicine where instruction is of a high type. No degrees are conferred by this school, applicants having to pass the examination at Coimbra.

WILLIAM LEE HOWARD, M.D.

The Physician and the Pharmacopeia.

NEW YORK, Feb. 18, 1906.

To the Editor:—I thank you for your courtesy in printing my letter with the above title in your pages (February 17, p. 526). Your answer, however, requires a reply on my part. You say: "We do not believe anyone suggests that we should be limited to Pharmacopœial preparations." And further you make the statement: "Our correspondent, like too many others, has set up a straw man to knock down." Now, I am not given to setting up straw men, and I am not very likely to make absurd statements, when the subject of proprietary remedies is under discussion, as I have studied the question from all sides, in all its phases, and at a time when too many who show now such commendable zeal on the subject were an absolute *terra incognita*. I could name you a dozen good, but ignorant men, who just did show themselves so narrow-minded and so bigoted as to condemn—condemn utterly—every proprietary and non-Pharmacopœial preparation. But I can do better than that. In THE JOURNAL of the American Medical Association, January 20 (p. 221, col. 1), Dr. Frank G. Whentley makes the statement that "the time has come when there are no ethical preparations. We should ignore the whole list. If we will confine our prescribing to articles recognized by the national authority, [The Pharmacopœia], we shall confer one of the greatest boons on the public, and incidentally on ourselves, that the annals of medicine record." And on the same page, column 2, Dr. James C. White is reported as saying, that "though in practice fifty years he had never prescribed a single remedy outside of those contained in the Pharmacopœia." (I wonder if he used cocaine between 1884 and 1894, as it was only in the latter year that cocaine became official, while Koller discovered it in 1884.) So you see, there are men, so ill-informed, so narrow-minded, as to advocate the non-use of any non-Pharmacopœial preparations. And it was against them that my letter was directed. For I fear that through excess of zeal, through misdirected energy, through intemperate statements of ill-informed persons, who are not familiar with the actual needs of the every day practitioner, our entire work, our labor for years, may go for naught.

WILLIAM J. ROBINSON, M.D.

Poison Ivy.

WASHINGTON, D. C., March 6, 1906.

To the Editor:—In THE JOURNAL, Jan. 27, 1906, page 301, you quote from the *Cincinnati Lancet-Clinic* from an article by Dr. E. S. McKee on the subject of poisoning by poison oak or ivy. Is it possible that the work of Pfaff, published in the *Journal of Experimental Medicine* (1897, vol. 5, No. 2), is not yet known to the profession?

Dr. McKee "has been poisoned twice by these plants and feels that he knows many times more about the trouble than he possibly could have known had he not had this experience." I have been poisoned about eighty times and feel that I also know something of the condition.

As a result of the work of Pfaff, we know that the irritant substance of *Rhus toxicodendron* and *Rhus venenata* is a fixed oil which is soluble in alcohol and which is precipitated by lead subacetate. The oil is similar to carbol, but is probably not

identical. The use of lead salts in dermatitis resulting from action of the oil is rational, but the precipitated lead compound must be removed from the skin as it is gradually decomposed; the oil is set free and its action continues.

The use of soap and water and a good hand brush is the simplest method of getting rid of the oil. The action is entirely mechanical and is perfectly efficient. Alcohol dissolves and removes the oil, but successive portions must be allowed to flow over the affected part, as, after contact, the alcohol may contain sufficient oil to spread the irritation. Ordinary alcohol must be used and not 50 per cent. alcohol, as the latter does not dissolve the oil. The action is purely a solvent one and not one of neutralization.

In every case the above methods of treatment are at once effective; further irritation is stopped and healing of the lesions begins. In some cases when actual sloughing has taken place a week or two may be necessary for complete healing, but ordinarily two or three days' time is sufficient. The use of ointments or fatty substances is both theoretically and clinically wrong, as such substances serve only to spread the oil.

It should be remembered that the clothing may have been in contact with the plants and that oil may be transferred from it to the skin and the irritation continued in this way. I have been poisoned by handling shoes worn while collecting the plants a year previously. Pollen from the flowers contains sufficient oil to give rise to a dermatitis in unusually susceptible persons.

A. W. BALCH.

P. A. Surgeon, United States Navy.

American Association of Medical Journal Advertisers.

MEMPHIS, TENN., March 10, 1906.

To the Editor: I am sending herewith for publication in THE JOURNAL copy of constitution of the American Association of Medical Journal Advertisers. This constitution has been agreed on through correspondence between the medical directors of a number of institutions as the basis of a temporary organization to stand until the annual meeting to be held in connection with the session of the American Medical Association in June. It will come up for confirmation or amendment at that meeting. Owners or superintendents of institutions who are in accord with the objects of this organization, who have not already been reached by direct correspondence, are requested to send their application for membership to the secretary.

GEO. E. PETTEY, Secretary.

CONSTITUTION OF THE AMERICAN ASSOCIATION OF MEDICAL JOURNAL ADVERTISERS.

NAME.

This Association shall be known as the American Association of Medical Journal Advertisers.

OBJECT.

To assist in maintaining proper ethical standards and for the advancement of truth and of the public welfare.

To establish and promulgate definite rules of conduct with reference to various questions which arise in institution work, which questions are left open to more or less doubt and to variable constructions, by the general provisions of the Principles of Medical Ethics of the American Medical Association.

MEMBERSHIP.

Membership in this association shall be limited to physicians who are responsible owners, superintendents or medical directors of "reputable" institutions devoted to the treatment of mental and nervous diseases and of alcohol and drug addicts who subscribe to the Principles of Medical Ethics of the American Medical Association.

OFFICERS.

The officers of the association shall be a president, a vice-president and a secretary, who shall be elected annually at a meeting to be held at the time and place of session of the American Medical Association, and shall hold their offices for one year and until their successors are elected.

The president and vice-president shall discharge such duties as are incumbent on a presiding officer.

The secretary shall be the executive officer of the association and shall conduct the correspondence, keep the records and transmit such other business as may be committed to him by vote of the Association or by direction of the executive committee.

The president, vice-president and secretary and two other members, to be elected annually, shall constitute an executive committee to have authority to pass on and decide all matters affecting the interest of members or applicants for membership, which may arise and require action in the intervals between the meetings.

The secretary shall keep an account of the expense incurred in conducting the correspondence and in carrying out any other orders of the association and the same shall be prorated among the members and paid annually.

MEETINGS.

This association shall meet annually at the time and place of meeting of the American Medical Association.

GENERAL PROVISIONS.

Since advertising in medical journals is the principal means to the members of this association have in bringing their work to the notice of the profession and since it is unsatisfactory and unfair for men who have won an honorable place in the profession by conscientious and diligent study and by honorable and fair dealing to be brought into competition, on terms of equality, with irregular and disreputable institutions, this is done when the advertisements of such disreputable institutions appear in the pages of the same journals containing the cards of institutions of good standing, therefore the members of this association pledge themselves not to run an advertisement in any medical journal or medical directory which admits to its pages the advertisements of irregular institutions.

Any institution or physician guilty of any of the following acts shall be deemed irregular for the purposes of this organization.

1. Use of a secret remedy or secret form of treatment.
2. Publishing testimonials of cures.
3. Guaranteeing cures.
4. Sending out prepared or home treatments for drug addicts.
5. Paying commissions to physicians for sending patients.
6. Advertising in the lay press in any manner except the insertion of a simple card giving the name and location of the institution or physician, class of patients treated, office hours of the superintendent or medical director and telephone number; provided, however, that the publication shall be confined to the lay press of the county in which the institution or physician is located.

[Explanatory Note.—The reason for each of the provisions above given would seem sufficiently clear, except probably the fourth. To those who have not given attention to such matters it might seem that to prohibit the sending out of home treatments for the drug addicts would be an unreasonable restriction and one that would interfere with the natural rights of individuals and of physicians, but that is not the purpose of the rule. The reason for such restrictions is this: In almost every instance remedies advertised as home cures for the morphin and other drug addicts are merely some concealed form of opiate. It is not difficult to switch the drug user from his morphin or other opiate on to the "cure," which he is assured is merely a harmless tonic. This assurance he accepts as true and under the belief that he has been freed from his drug slavery and in the buoyancy and hope that such a deliverance would bring, he writes glowing testimonials of his cure while still under the influence of the supposedly harmless tonic. When he attempts to leave off this tonic, he finds that he is totally unable to do so, in fact that he feels as much a slave to the "cure" as he was to his original drug, and that now, instead of being able to buy his drug supply in the open market at a reasonable price, he is compelled to send ten or more dollars per month to his home cure vendor for his drug supply, as he can not readily leave it off and resume his former drug. These "cures" usually contain a combination of narcotics by the use of which the victim acquires a double or triple addiction instead of the single one which he had before the use of such "cure." These home treatments do not really cure the morphin or other drug addiction. This fact is known to their vendors as well as to us, therefore we are compelled to conclude that one who continues to advertise and send out such a "cure" does so with fraudulent intent, and is, therefore, unworthy of association with gentlemen, and should not be allowed to practice his deception on unsuspecting public by using space in the columns of medical journals.]

Marriages

W. H. BUREL, M.D., Prairieburg, Iowa, to Miss Dolan, recently.

WILLIAM H. BUTTRAM, M.D., to Miss Cora Tipton, both of Niotra, Tenn., recently.

W. J. WEST, M.D., Knoxville, Tenn., to Miss Alice V. Naylor of Little Rock, Ark., March 1.

WILLIAM M. COOLEY, M.D., to Miss Ella Victoria Engstrom, both of Peoria, Ill., February 21.

GEORGE LAMB BUST, JR., M.D., to Miss Adelaide Richardson, both of Brooklyn, N. Y., February 27.

WILLIAM JESSE JENNINGS, M.D., to Miss Sarah Tillman Flowers, both of Lakely, Ga., March 6.

SCHUYLER COLFAX GRAVES, M.D., Grand Rapids, Mich., to Miss Caroline E. Launt of Walker Township.

HARRY F. RIBEL, M.D., to Miss Clara Sander, both of Le Mars, Iowa, in Sioux City, Iowa, February 26.

FRANK THOMAS RIDLEY, M.D., Frederick, Va., to Miss Nellie Morris Godwin of Charlottesville, Va., March 14.

A. LEO FRANKLIN, M.D., Cumberland, Md., to Miss Lelia Weston Jordan at Charlestown, W. Va., March 8.

H. B. JOHNSON, M.D., Pomona, Kan., to Miss Agnes Charlotte Thestrup of Williamsburg, Kan., March 6.

RALPH WALDO LOEBENSTEIN, M.D., New York City, to Miss Anne Murrell Williams of Ocala, Fla., at Flushing, N. Y., March 8.

Deaths

Charles Augustus Lindsley, M.D., one of the foremost sanitarians of America, died suddenly at his home in New Haven, Conn., March 9, aged 79. His death was due to heart disease, from which he had suffered for several years. He was born in Orange, N. J., Aug. 19, 1826; was graduated from Trinity College, Hartford, with the degree of A.B. in 1849, and received his M.A. degree in 1852. He studied medicine at the College of Physicians and Surgeons in the City of New York and in the Medical Institution of Yale College, New Haven, and was graduated from the latter institution in 1852. From 1860 to 1883 he was professor of materia medica and therapeutics at this institution; from 1883 to 1897, professor of theory and practice of medicine, and thereafter emeritus professor; dean of the faculty from 1863 to 1885, and lecturer on sanitary science from 1898 to 1899. He was attending physician at the Connecticut State Hospital from 1861 to 1876, and secretary of the General Hospital Society of Connecticut from 1865 to 1877. He was health officer of New Haven from 1874 to 1888.

His society affiliations were numerous; he was president of the New Haven Medical Association in 1877; president of the New Haven County Medical Association, 1875-1876; president of the Connecticut Medical Society in its centennial year, 1892. For many years he was a member of the American Medical Association, and its vice-president in 1890, and orator in State Medicine in 1892; vice-president of the American Public Health Association in 1877, and president of the International Conference of State and Provincial Boards of Health from 1893 to 1895. He was also an honorary member of the state medical societies of New York and New Jersey.

He was made a member of the Connecticut State Board of Health in 1878, and has been its secretary and executive officer since 1884. He has been vice-president and president of the New Haven Dispensary from the time of its foundation in 1872. He has been a prolific writer on subjects connected with public health and sanitation. His greatest work was as secretary and executive officer of the State Board of Health, which under his wise administration has become one of the most noteworthy in the United States. Dr. Lindsley was also a pioneer in the investigation of typhoid fever epidemics in the state.

Samon R. Hewett, M.D. Rush Medical College, Chicago, 1867; local surgeon at Charles City, Iowa, of the Chicago, Milwaukee & St. Paul Railway; health officer of Charles City; a member of the International Association of Railway Surgeons, Austin Flint-Cedar Valley Medical Society, and for many terms president of the Floyd County Medical Society; assistant surgeon in the United States Marine-Hospital Service during the Civil War, died at his home in Charles City, March 4, from heart disease, aged 75.

Henry Emory Rothe, M.D. College of Physicians and Surgeons in the City of New York, 1880; deputy county physician of Hudson County from 1879 to 1895; hospital steward during the Civil War; treasurer of Harrison, N. J., and assessor of the Third Ward of Newark for nine years, died at his home in Harrison, Newark, March 4, from cerebral hemorrhage, after an illness of six days, aged 65.

Lewis Williams, M.D. Miami Medical College, Cincinnati, 1857, a member of Grant County (Ind.) Medical Society, died at his home in Marion, March 5, after a long illness from senile debility, aged 89. The medical society held a special meeting March 7, passed resolutions regarding the death of Dr. Williams, and voted to attend the funeral in a body.

John F. Dyer, M.D. Medical Department of Western Reserve University, Cleveland, 1902; a member of the American Medical Association, the North Texas Medical Society, and president of the Lamar County Medical Society in 1904; formerly a practitioner of Chisota, Texas, died at his home in Mineral Wells, Texas, Nov. 23, 1905, aged 39.

Henry T. Calkins, M.D. University of Louisville, Medical Department, 1869; said to have been the oldest practitioner in northern Michigan; a member of the American Medical Association and of the Michigan State Medical Society; division surgeon of the Grand Rapids & Indiana Railroad; health officer of Potoskey, Mich., died suddenly at his home in that city, from heart disease, March 5.

Charles Boaz Whitfield, M.D. College of Physicians and Surgeons in the City of New York, 1871; member and sometime president of the Marengo County (Ala.) Medical Society; a veteran of the Civil War, was found dead in the road about five miles from his home in Demopolis, Ala., March 1, supposedly from heart disease, aged 67.

James M. Selfridge, M.D. Jefferson Medical College, Philadelphia, 1856; one of the founders of Fabiola Hospital, Oakland, Cal.; attending physician to the State Institution for the Deaf, Dumb and Blind from 1872 to 1878, died at his home in Oakland, March 4, from cancer, after an illness of several years, aged 81.

Arthur R. Cobb, M.D. Hahnemann Medical College, Philadelphia, 1891, of Philadelphia, died in the Hahnemann Hospital in that city, March 2, from injuries received as a result of jumping from the window of a cottage in Cape May, N. J., February 17, while suffering from delirium consequent on overwork, aged 35.

R. C. Volker, M.D. Central College of Physicians and Surgeons, Indianapolis, 1872, formerly medical director of the St. Louis, Iron Mountain & Southern Railway, and in charge of the railway hospital at Fort Smith, Ark., died at his home in St. Louis, February 22, after an illness of six months, aged 67.

Martyn Taylor, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1852; one of the oldest practitioners of Scioto County, Ohio; acting assistant surgeon in the Army during the Civil War, died at his home in Sciotoville, March 3, after an illness of several weeks, aged 78.

Frank L. Wisdom, M.D. New Orleans School of Medicine, 1860, captain and surgeon in the Confederate service during the Civil War, and chief of staff at the Division Hospital, Brunswick, Ga., in 1861, died suddenly at his home in Texarkana, Texas, March 1, from heart disease, aged 70.

Ira H. Gillum, M.D. Rush Medical College, Chicago, 1874; a veteran in the Civil War; a member of the Indiana legislature; chairman of the Iroquois County (Ill.) board of supervisors, and alderman of Milford, Ill., died at his home in that city, March 7, from cerebral hemorrhage.

John Harris Pettee, M.D. Harvard University Medical School, Boston, 1897, of Boston, died at the home of an acquaintance in Newton Highlands, Mass., from general collapse, due to worry over the publicity attending his connection with the "dress suit-case mystery," March 5.

John Phillips, M.D. Medico-Chirurgical College, Philadelphia, 1904, of Lickdale, Pa., formerly resident physician in the Allentown Hospital, died in the Lebanon Hospital, February 23, from septicaemia following a mastoid operation, after an illness of three weeks, aged 28.

David D. Richardson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1871, chief resident physician of the State Hospital for the Insane, Norristown, Pa., died suddenly from heart disease, in his apartments at the hospital, March 6, aged 60.

John P. Cotton, M.D. Medical College of Ohio, Cincinnati, 1842; a member of the American Medical Association, and for more than sixty years a practitioner of Charleston, W. Va., died at his home in that city, March 3, after a lingering illness, aged 85.

John Eaton Pugh, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1853, of Abbeville, La., surgeon in the Confederate service during the Civil War, died at the home of his son-in-law, near Napoleonville, La., February 27.

James L. Jones, M.D. Montana State Board, 1889; coroner of Beaverhead County for two terms and county physician in 1892, died at his home at Wisdom, Mont., February 25, from heart disease, after a prolonged illness, aged 48.

C. R. Mason, M.D. Cincinnati College of Medicine and Surgery, 1870, one of the wealthiest practitioners of Hartford City, Ind., was found dead in his office, March 7, aged 60.

Simon G. Miller, M.D. Bellevue Hospital Medical College, New York City, 1874, of Francis, Fla., was run over by a train near his home and instantly killed, January 17, aged 59.

C. A. LINDSLEY, M.D.

Andreas A. Naegeli, M.D. Medical College of Indiana, Indianapolis, 1885, one of the foremost practitioners of Sibley County, Minn., died at his home in Gibbon, from dilatation of the heart, March 3, after an illness of only a few hours, aged 64.

J. P. Bowers, M.D. University of Louisville, Medical Department, 1872, of Fort Worth, Texas, committed suicide at Sanger, Texas, by cutting his throat, February 27, while despondent from ill health and financial reverses, aged 61.

Robert C. Hutchinson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1880, surgeon of the American line steamship *St. Louis*, died at sea, from pneumonia, February 27, after a short illness, aged 49.

Joseph A. Tipton, M.D. New York University, New York City, 1860, surgeon both in the Confederate army and navy during the Civil War, died at his home in Roanoke, Va., March 5, after a long illness, aged 69.

Sanford W. Adams, M.D. University and Bellevue Hospital Medical College, New York City, 1899, police surgeon of Mount Vernon, N. Y., died at his home in that city, March 7, after an illness of three months, aged 29.

Stuart A. Watson, M.D. University of Louisville, Medical Department, 1873, a prominent practitioner of Bastrop County, Texas, died at his home in Elgin, March 3, from pneumonia, after an illness of eight days.

Matthew Wallace, M.D. University of the Victoria College, Coburg, Ont., 1881, died at his home in Toronto, March 3, from malignant disease, for which an operation was performed in September last, aged 57.

George W. Williams, M.D. Missouri Medical College, St. Louis, 1848, one of the oldest practitioners of Missouri, died at his home in Farmington, March 2, from senile debility, after a short illness, aged 87.

Isaac Newton Brown, M.D. Eclectic Medical Institute, Cincinnati, 1860, a surgeon in the Civil War, died at his home in Ironton, Ohio, March 1, from long-standing disease of the throat, aged 66.

Thomas A. Davis, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1851, of Selma, Ala., died in Tuscaloosa, Ala., February 27, from influenza, after a short illness, aged 82.

Charles H. Witham, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1875, a practitioner of Boston, died at his home in Cambridge, Mass., Dec. 24, 1905, aged 51.

Joseph Torkington, M.D. Jefferson Medical College, Philadelphia, 1885, died at his home in Pawtucket R. I., February 27, from pneumonia, after an illness of one week, aged 56.

Theodore F. Laing, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1883, of Locust Grove, Ga., died at a private sanitarium in Atlanta, Ga., March 2, aged 61.

Solomon Baird Wolfe, M.D. Shelby Medical College, Nashville, Tenn., 1862, of New York City, died suddenly from heart disease in his office, Dec. 14, 1905, aged 61.

Alexander P. Landry, M.D. Harvard University Medical School, Boston, 1870, died at his home in Eel Brook, Yarmouth, N. S., Nov. 6, 1905, after an illness of six weeks.

Elmer W. Heltman, M.D. Toledo (Ohio) Medical College, 1886, an oculist of Toledo, died at his home in that city, March 3, after an illness of six months, aged 44.

William Stross, M.D. Miami Medical College, Cincinnati, 1903, died recently at his home in Cincinnati from chronic nephritis after a prolonged illness, aged 48.

George W. Pleasanton, M.D. Hahnemann Medical College, Philadelphia, 1887, died suddenly at his home in Milford, Del., February 26, from heart disease, aged 45.

Miles Laha, M.D. Hospital College of Medicine, Louisville, 1893, died at his home in New Haven, Ky., February 21, from tuberculosis, after a long illness, aged 48.

William E. Swiler, M.D. Jefferson Medical College, Philadelphia, 1857, died at his home in Mechanicsburg, Pa., March 8, from cerebral hemorrhage, aged 73.

Vandy M. Neal, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1860, died at his home in Hillsboro, Miss., December 19, aged 70.

W. H. Burke, M.D. Rush Medical College, Chicago, 1902, of Prairieburg, Iowa, died March 1 from pneumonia, after an illness of less than two weeks.

Mabel Wells, M.D. Medical Department of the Johns Hopkins University, Baltimore, died at her home in Wellesley, Mass., March 3, aged 32.

Richard H. Kenning, M.D. College of Physicians and Surgeons, Manitoba, Winnipeg, 1883, died at his home in Chicago, March 6, aged 58.

James Macdonald, M.D. Harvard University Medical School, Boston, 1864, died at his home in Boston, March 8, from heart disease, aged 73.

William H. McCormick, M.D. Jefferson Medical College, Philadelphia, 1864, died at his home in Cumberland, Md., March 6, aged 80.

David M. McFall, M.D. Jefferson Medical College, Philadelphia, 1857, died at his home in Nashville, Tenn., Dec. 20, 1905, aged 72.

James Gates M.D. University of Louisville, Medical Department, 1882, died at El Paso, Texas, Oct. 22, 1905, aged 71.

Nelson H. Church, M.D. Rush Medical College, Chicago, 1869, died March 5, at his home in Chicago, aged 63.

Eugene S. Atwood, M.D. Rush Medical College, Chicago, 1877, died at his home in Chicago, March 2.

Deaths Abroad.

Max Nitze, M.D., professor of urology at Berlin and inventor of the cystoscope, died suddenly, February 22, aged 58. The twenty-fifth anniversary of this invention was celebrated in March, 1904, when honors were showered on Nitze, who was then only a privat docent.

Leon Colin, M.D., formerly inspector general of the French military sanitary service, and president of the Académie de Médecine, died recently at Paris.

Book Notices

MANAGEMENT OF A NERVE PATIENT. By A. T. Schofield, M.D. Author of "The Unconscious Mind," "The Force of Mind," "Unconscious Therapeutics," etc. (Cloth. Pp. 267. Price, \$1.50.) Philadelphia: P. Blakiston's Son & Co., 1906.

This little volume is largely in the same line as that of Dr. DuBois (which we reviewed March 10, page 744), and contains a valuable amount of useful suggestions and hints. The author does not discard medical and physical treatment, however, to the same extent or reject hydrotherapy and electricity as does DuBois. These all play a more or less prominent part in his therapy, and he considers that mental treatment has in it the danger of leading the specialist to consider it too much of a cure-all in itself. Every curative agent, he says, has more claimed for it than it deserves, and this is pre-eminently true of mental action in disease. He does not enter much into the psychology, but has much to say about the unconscious mind and thinks that certain individuals possess a sort of healing gift; he thinks this may be explained by some action on this unconscious mind. However one may view this as a vagary or otherwise, the main part of Schofield's work is sensible and clear and can be profitably read by the medical practitioner. In this country legitimate psychotherapeutics is not necessarily in discredit, however it may be in England; that country, he says, is so overrun with an invasion of American mystics (Eddyites?) that it is hard to obtain for psychotherapy a respectful hearing among medical men. It would be a good thing, however, if a little more systematic instruction on these points in psychiatric therapeutics were included in the medical curriculum, both here and elsewhere.

A TEXT-BOOK OF PHARMACOLOGY AND THERAPEUTICS, OF THE ACTION OF DRUGS IN HEALTH AND DISEASE. By A. R. Cushny, M.A. M.D. Fourth Edition. Thoroughly Revised. Illustrated with 53 Engravings. (Cloth. Pp. 752. Price, \$3.75 net. Philadelphia: Lea Brothers & Co., 1906.)

This work has been revised to conform with the new Pharmacopoeia and seems to be confined to pharmacopoeial preparations. The general arrangement of the text is the same as in previous editions. Part I is devoted to a consideration of organic substances acting locally. Part II takes up organic substances which act after absorption, and considerable space is occupied by discussion of the various anesthetics. Alcohol is mentioned under this head and attention is directed to the dangers attending the use of wood alcohol. In the chapters on ether and chloroform reference is made to Embley's researches, showing that fatal arrest of the heart's action frequently occurs at the beginning of the anesthesia through excessive inhibitory action. Acetanilid, though official in the U. S. Pharmacopoeia,

under this name, is referred to as antifebrin, the name by which this drug is known in the British Pharmacopœia. Part III deals with the alkalies, alkaline earths, acids and allied bodies. Part IV is devoted to a consideration of the heavy metals, and in Part V ferments, secretions and toxalbumins are discussed. Part VI takes up menstrua and mechanical remedies, and the book concludes with a classification of drugs according to their therapeutic action. Cushty's textbook has long been recognized as a standard and the new edition will add to the prestige it had already earned.

SURGICAL ASPECTS OF DIGESTIVE DISORDERS. By J. G. Mumford, M.D., in Association with A. K. Stone, M.D. Cloth. Pp. 395. Price, \$2.50. New York: The Macmillan Co., 1905.

The title of this book does not suggest its real contents. The first chapter describes "ancient conceptions of the digestive organs." It is a brief history of our knowledge of these organs. The second is an account of methods of clinically studying diseases of the stomach, such as physical, chemical, microscopic and x-ray examinations. The chapters following, however, are the ones which give greatest value to the book. The authors are to be congratulated on having written a readable and unusually instructive book. It is not a systematic treatise on diseases of digestive organs, but a collection of new facts and well-known ones bearing on the natural course and results of certain diseases and on the relative success of different kinds of treatment. It is quite as interesting and instructive to the physician as to a surgeon. The following titles of succeeding chapters will best explain the scope of the book: "The Stomach", "Dilatation of the Stomach Treated Without Operation", "Ulcer of the Stomach and Duodenum", "Operative Intent of Non-Malignant Disease of the Stomach", "Cancer of the Stomach", "The Bile Passages", "Surgery of the Bile Passages", "The Pancreas", "Abdominal Ptosis", "The Appendix Vermiformis."

There is in these chapters much statistical matter which is new, well analyzed and important. The judgments of the authors are conservative and rarely deserve criticism.

REFRACTION, Including Muscle Imbalance and the Adjustment of Glasses. By R. S. Crandall, A.M., M.D., and A. E. Hershoff, M.D. Cloth. Pp. 144. Price, 1.50 net. Philadelphia: Boerlcke & Tafel, 1906

Although within recent years there have been many publications dealing with the problems of refraction, muscular insufficiency and the correct adjustment of lenses for ocular purposes, we believe that none of them is better suited to the beginner than this small work. It is sufficiently illustrated with good, clear cuts, and the literary portion of it is everything that one could desire. No doubt the authors might easily have added to (or, perhaps, padded) their small work, but in the absence of such elaboration we believe that it will have a wider sale than many a larger treatise. If we were disposed to criticize the work from the textbook standpoint the principal objection we would raise is to the small space devoted to skiagraphy. That important objective test is not as carefully or as fully considered as it ought to be. On the whole, however, the book is a very useful compendium and can be safely recommended to students of elementary ophthalmology.

MANUALE DELLE MALATTIE DELL'OCCHIO Ad Uso Degli Studenti E Dei Medici. Pratiche Traduzione Italiana Sulla Quarta Edizione Americana. Con note ed Aggiunte del Dr. Edmondo Trombetta and Dr. Carlo Enrico May. Con 360 illustrazioni originali e 21 Tavole con 70 figure colorate. Cloth. Pp. 555. Price 8 lire. Turin: S. Torino: Unione Tipografico-Editrice, 1906.

This is the Italian translation of Dr. C. E. May's well-known work on diseases of the eye, with notes by Dr. Trombetta, instructor in ophthalmology in the University of Turin. It does not differ in any essential respect from the original work, so well known to American students of ophthalmology. As stated in the Italian edition, a number of additions have been made to this textbook, of which Italian readers will reap the benefit. We have reviewed the various editions of this excellent work of Dr. May's and have nothing to add to what has been previously said, except that we have reason to congratulate ourselves that the writings of American authors are beginning to be better appreciated in foreign countries than they have been in times past. We hope and believe that the Italian edition will receive as cordial a welcome as the four American, one British and the German editions of this popular manual.

Miscellany

Epidemics of Yellow Fever in Maryland.—At the last meeting of the General Alumni Association of the University of Maryland, Dr. James Carroll read an interesting paper on this subject. He referred first to the fact that Dr. Nathaniel Potter, a pupil of Dr. Benjamin Rush, and first professor of medicine in the university, held the view that yellow fever was not directly contagious. Dr. Potter believed that he was the only person in America who held that opinion at that time and prepared to defend his belief in an inaugural thesis to be read at the commencement exercises of the University of Pennsylvania. He was dissuaded from this, however, on the grounds of propriety and expediency. Dr. Carroll said that on account of its importance as a seaport, Baltimore must have been the seat of many outbreaks of this disease, yet the only recorded epidemics occurred in the years 1794, 1797, 1800 and 1819. He called attention to the important fact that all the epidemics originated at Locust Point or along the wharves and can be traced directly to the shipping. This is not to be wondered at, as the city was in constant communication with the West Indies. In these days yellow fever was frequently confounded with malaria, and it was sometimes contended that the two diseases were identical. The general restriction of the disease to certain localities and the fact that persons who visited these localities even for only a few hours proved that the disease was one of locality. It was also observed that if the wind blew strongly from the infected district toward the city, within a few days yellow fever appeared in the city. From this it was concluded that the poison must exist in the atmosphere and must be transported by the wind. It was recorded by a Baltimore physician that during an epidemic mosquitoes became an intolerable pest, while only a short time before no mosquitoes were observed. This observation, Dr. Carroll states, agrees with our present knowledge of the facts that the yellow-fever carrying mosquitoes can be conveyed by vessels from one place to another, that in the warmer seasons they breed on shore and that they become infected only after feeding on a patient. This also explains why shipping localities were infected while other places equally favorable for the development of the disease escaped. In the epidemic of 1794 Dr. Drysdale reported that he saw his first case August 7, at Bowley's wharf, and that on August 14, 20, 22 and 23, he saw five additional cases at the same place. Other interesting references to this epidemic were published by Dr. John B. Davidge. Three physicians investigated the cases reported by Dr. Drysdale and stated that the disease was "the common epidemic of the season," "the bilious remittent fever." The outbreak of 1819 followed the arrival of an infected ship from Havana. The fever appeared in July and persisted till the end of October. Among the records of this epidemic are letters and other documents published by order of the mayor, and containing the actual experiences of several physicians. These records show a remarkable unanimity of belief that yellow fever was not contagious.

Foundation of a Medical Society for Demonstrations Only.—At the meetings of most medical societies the demonstration of patients and specimens is secondary in importance to the discourses. When too much attention is devoted to them, the scientific papers are belated. A number of physicians in Berlin have organized an informal society for demonstrations only, each demonstrator being limited to ten or fifteen minutes and only five minutes being allowed for discussion at the time. When it is desired to have discussions exceed this limit they must be transferred to the arena of the already established medical societies. The first meeting of the new organization was held in January. Among others, Brieger exhibited specimens of syphilitic lesions of the liver, simulating tumors, while Karewski presented some patients with these lesions, incorrectly diagnosed at first. Altmann exhibited cases of stenosis of the pylorus and Pinkus demonstrated the *Spirochaeta pallida*. The society bears the euphonic name of the "Zwangslose Demonstrations-gesellschaft." The description in the *Allg. Med. Ct.-Ztg.* states that the meetings are held at the amphitheater, Ziegelstrasse 18.

Toxicity of Bile.—Meltzer and Salant state that according to the present almost universally accepted view, bile contains a toxic element which is capable of producing nervous depression, coma and paralysis, but does not contain any element which can produce excitation and convulsions. They conducted a series of experiments, however, which proved that, contrary to this generally accepted view, the bile does contain a tetanic element, or an agent which causes increase of excitability of the nervous system. The experiments demonstrated that bile from the common duct of many rabbits causes marked hyperesthesia and tetanic attacks when injected into frogs; stagnant bile (as in the gall-bladder) invariably produces coma and paralysis; the depressive and exciting elements of the bile are mutual antagonists, the effect of both, when simultaneously present, being that of an algebraic sum; the depressive element, when present in a highly effective dose, is the stronger of the two, while the tetanic element becomes effective apparently in a dose far below that which constitutes the minimum for the depressive element.

Death from Thirst.—Dr. W. J. McGee, director of the St. Louis Public Museum, formerly chief of anthropology of the Louisiana Purchase Exhibition, discussed this subject before the St. Louis Medical Society. He has recently made observations in the arid regions of Arizona, and he reported the case of a Mexican who was lost in the desert without drink for eight days. He traveled 108 miles in a stuporous condition and, half dead, finally stumbled into Dr. McGee's camp, where he was revived after great difficulty. Dr. McGee called attention to thirst as a disease, treating of physiologic thirst, thirst beyond physiologic limits and thirst in extremis. The last might be called living death; death of the tissues takes place from below upward, owing to the impoverished state of the blood and to want of circulation. The victim's toes drop off and breaks in the skin do not bleed because of the non-fluid state of the blood.

Suprarenal Preparations in Treatment of Hemorrhagic Purpura.—M. Labbé of Paris has recently reported a case of severe "myeloid purpura." No treatment proved effectual until a suprarenal preparation was given. Even 4 gm. of calcium chloride a day failed to prevent the appearance of the severe hemorrhages. They were apparently uninfluenced until a small amount of a suprarenal preparation was injected subcutaneously every day. The hemorrhages ceased at once from the first injection. The aspect of the tissues also changed, the skin became pale and exsanguinated, and it was difficult to draw blood from the finger tip. The suprarenal preparation evidently induced intense vasoconstriction. The results suggest that the trouble in purpura is not so much in the blood itself as in the vessels. *Bull. de la Soc. Méd. des Hôp. de Paris*, Dec. 28, 1905.

The Doctor.—In the name of thousands of unbroken homes in which midnight hand-to-hand fights with death have been fought and won; in the name of thousands of lives rescued from abnormality and made useful; in the name of unshed tears and forestalled pain and baffled death—I doff my hat to-day to The Doctor. May he never have use for his own medicine. May each moment of pain he has saved others shine in the crown of his life like a bright star. May the children to whom he has saved parents and the parents to whom he has saved children take time to acknowledge the doctor's worth. May his patients pay him his bill. And in the inevitable hour may a certain grim adversary recognize a noble foe and deal gently with the doctor.—W. J. C., in *Detroit News*.

Campaign Against Tuberculosis in Spain in the Seventeenth Century.—The records of the city of Valencia bear a decree dated 1698 demanding that physicians must inform the municipal authorities when they encounter a case of consumption, and that the clothing and bedding used by a consumptive shall be burned after his death, with the exception of metal articles. A large fine is imposed for buying articles known to have been used by deceased consumptives, and also for neglect to declare the cases to the authorities. The decree provides for the public proclamation of its provisions in all parts of the town by the town crier. The fac simile of the quaint wording and seal is given in the *Siglo Medico* No. 2641, 1904.

Queries and Minor Notes

COMPOSITION OF CASTORIA.

MCBAIN, MICH., March 1, 1906.
To the Editor:—Two years ago I was called to attend a baby aged one week. The father had given it, so he said, only half a teaspoonful of castoria. When I saw the child it was dying, and breathed its last half an hour later. A few weeks ago I was called to attend a child of 10 months, suffering from diarrhea. The parents gave hardly any answer to questions. The child was comatose, the pupils did not react to light, pulse was 132, and the body was cold. The parents said that the child had had innumerable passages. Two days later, when the child was better, I learned that they had given it five teaspoonfuls of castoria within a short time. I would like to know the ingredients of castoria. Can you give me this information?
J. G. REINBERG, M.D.

ANSWER.—According to the patent, the formula is as follows: To 125 pounds of senna leaves add 35 gallons of water at 65° C., in which has been dissolved 48 ounces of sodium bicarbonate. Exhaust the senna by percolation until 240 pounds are obtained. In this dissolve 210 pounds of sugar and 4 ounces of Rochelle salts, then add spirits of gaultheria, 18 pints, and spirits of peppo, spirits of chenopodium (wormseed), spirits of peppermint and spirits of anise, of each 2 ounces.

CHARITIES AND THE COMMONS.

TISKILWA, ILL., March 10, 1906.
To the Editor:—In your issue of March 10, 1906, under title of "Public Instruction in Sexual Hygiene," page 729, you speak of the periodical *Charities and the Commons*. Where can I get this paper?
C. F. HORNBER.

ANSWER.—*Charities and the Commons* is a weekly review of philanthropy and social advance, published under the Charities Publication Committee of the New York Charity Organization Society, 105 East 22d St., New York, and edited by Edward T. Devine, Graham Taylor and Paul U. Kellogg. The first weekly issue of each month appears as an enlarged magazine number. Subscription, two dollars a year. Single copies, ten cents each.

DISCUSSION WANTED ON CONTRACT PRACTICE.

YORK, PA., March 6, 1906.
To the Editor:—I would like to have your opinion relative to some important questions that threaten the dignity and usefulness of the medical profession. Recently I was appointed chairman of a committee "to investigate the propriety of contract practice and to make a report at the next regular business meeting of the York County Medical Society as to what forms of contract practice this committee considers consistent, and what forms inconsistent with the Principles of Ethics of the American Medical Association." Is life insurance work contract practice? Is any or all of it, mere inspections for twenty-five cents, and examinations for which from three to five dollars are paid, consistent with the Principles of Ethics of the American Medical Association? Is there anything inconsistent in the contract practice of railroad surgeons? Likewise of physicians who accept contract work of operators of mines and factories? Also of physicians who accept temporary contracts of construction contractors who employ foreign labor in the construction of railroads, trolley lines, reservoirs, sewer systems, etc.? What would you say of physicians who accept a contract to attend members of clubs and secret organizations for \$1.50 a year, or \$2 a year per member, and do all the work in said member's family, except to attend labor cases and venereal diseases? These questions are beginning to assume serious aspect in some sections, and we believe they are better dealt with in the beginning than later. What action has been taken by other societies to prohibit contract practice which is inconsistent with the Principles of Ethics and derogatory to the dignity and usefulness of the medical profession?
G. E. HOLTZAPFEL.

ANSWER.—The questions asked above are important ones, and have been asked by many other correspondents during the last three or four years. We have discussed the subject in some of its phases several times (see *THE JOURNAL*, Dec. 9, 1903, p. 1817; Jan. 27, 1904, p. 225; Feb. 17, 1904, p. 517; Oct. 29, 1904, p. 1222; Feb. 15, 1904, p. 1158; Sept. 10, 1904, p. 742; Oct. 8, 1904, p. 1067; Feb. 29, 1904, p. 548). And we believe that a discussion in our paper will be valuable. We would especially like to hear what societies have already acted on the matter, and what action was taken. It is a subject that has caused our profession in other countries serious trouble, and is already a difficult problem with us in many localities. The Principles of Medical Ethics refers to the matter only in a general way. Section 1 of Article VI says: "By the members of no profession are eleemosynary services more liberally dispensed than by the medical, but justice requires that some limits should be placed to their performance. Poverty, mutual professional obligation, and certain of the public duties named in Sections 1 and 2, of Chapter III, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or the rich, or by societies for mutual benefit, for life insurance, or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege."

State Boards of Registration

COMING EXAMINATIONS.

GEORGIA Medical Examining Board (Regular), the Capitol, Atlanta, April 7. Secretary, E. R. Anthony, Griffin.

UTAH State Board of Medical Examiners, Salt Lake City, April 2. Secretary, R. W. Fisher, Salt Lake City.

ARIZONA Board of Medical Examiners, Phoenix, April 2-3. Secretary, Axel Martin, Phoenix.

CALIFORNIA Board of Medical Examiners, San Francisco, April 2-3. Secretary, Charles L. Tisdale, San Francisco.

IDaho State Board of Medical Examiners, Pocatello, April 3. Secretary, J. D. Conant, Jr., Genesee.

MONTANA Board of Medical Examiners, Senate Chamber, the Capitol, Helena, April 3. Secretary, William C. Riddell, Helena.

NORTH DAKOTA State Medical Examining Board, Grand Forks, April 3. Secretary, H. M. Wheeler, Grand Forks.

OHIO Board of Registration and Examination, State House, Columbus, April 3. Secretary, D. N. Kinsmann, Columbus.

MINNESOTA State Board of Medical Examiners, State Capitol Building, St. Paul, April 3-5. Secretary, O. E. Linjer, Minneapolis.

MISSOURI State Board of Health, Kansas City, April 3-5. Secretary, J. A. B. Adeock, Warrensburg.

RHODE ISLAND State Board of Health, State House, Providence, April 5. Secretary, Gardner T. Swaps, Providence.

ARKANSAS State Board of Medical Society, Little Rock, April 10. Secretary, J. P. Runyon, Little Rock.

MISSOURI State Board of Health, St. Louis, April 10-12. Secretary, J. A. B. Adeock, Warrensburg.

WEST VIRGINIA State Board of Health, Parkersburg, April 10-12. Secretary, H. A. Barbee, Point Pleasant.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, D. C., April 12. Secretary, William C. Woodward, Washington, D. C.

ILLINOIS STATE BOARD OF HEALTH, Great Northern Hotel, Chicago, April 18-20. Secretary, J. A. Egan, Springfield.

Maryland December Report.—Dr. J. M. Scott, secretary of the Board of Medical Examiners of Maryland, reports the examination held at Baltimore, Dec. 13-16, 1905. Of the 62 applicants who were present, 23 participated in the examination for the first time, of whom 16 were successful. Thirty-four applied for re-examination in branches in which they had previously failed; of these 15 were successful, working off all branches. Primary examinations require a general average of 75 per cent. Those re-examined are required to make 75 in each branch. Three took the examination for second year students and have completed studies in anatomy, chemistry, materia medica and physiology. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent
Johns Hopkins University,	(1902) 89; (1903) 87; (1904) 88		
University of Pennsylvania	(1904) 89		
Howard University	(1905) 80, 82, 88		
University of Maryland,	(1904) 87; (1905) 80, 80, 85		
College of P. and S., Boston	(1905) 75

Baltimore Med. Coll.,	(1905)*		

* Re-examined, no percentage assigned.

† Graduates of this institution (the character of which is well known) were at first refused recognition by the board, but a writ of mandamus was sued out against it, and on a hearing and examination of the law presiding what colleges should be recognized by the board of medical examiners, the court ordered that as this institution was legally incorporated, its graduates should be received by the Board of Medical Examiners of Maryland. The court ruled, furthermore, that under the last amendment, correction, hours of study, etc., could not be considered if the institution was legally incorporated; therefore the board was obliged to receive the graduates of this institution.

Virginia December Report. In the report of the examination held at Richmond in December, 1905, published in THE JOURNAL, Feb. 21, 1906, page 608, it is stated that a graduate of the Medio-Chirurgical College of Philadelphia failed. This is an error; it should have been the Medio-Chirurgical Department of Christ Institute, Baltimore.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending March 10, 1906:

Kirby-Smith, R. M., asst.-surgeon, advanced to rank of captain from February 25, 1906.

Appel, D. M., deputy surgeon-general, relieved from duty in the Philippines Division to take effect at such time as will enable him to comply with the order, and to proceed on transport sailing from Manila, P. I., after April 27, 1906, to San Francisco, where, on arrival, he will report by telegraph to the military secretary of the Army for further orders.

Wales, Philip G., surgeon, relieved from duty in the Philippines Division, and will proceed on transport sailing from Manila, P. I., after July 1, 1906, to San Francisco, where, on arrival, he will report by telegraph to the military secretary of the Army for further orders.

Whitmore, E. R., asst.-surgeon, relieved from duty at Fort Jay, N. Y., and ordered to Fort Warren, Mass., for duty.

Keefer, Frank R., surgeon, having reported at San Francisco, in compliance with orders heretofore issued, will proceed to the Presidio of Monterey, Cal., and report to the commanding officer of that post for duty.

Clayton, J. E., asst.-surgeon, granted 2 months' leave of absence, to take effect on being relieved from temporary duty at the United States Military Prison, Fort Leavenworth, Kansas.

Page, Henry, asst.-surgeon, on arrival at San Francisco, will proceed to Fort Leavenworth, Kansas, and report to the commandant of the United States Military Prison at that post for duty, and by letter to the commanding general, Department of the Missouri, relieving Captain Jere B. Clayton, asst.-surgeon.

Woodbury, Frank, asst.-surgeon, advanced from grade of first lieutenant to that of captain, from March 6, 1906.

Shook, Jay R., asst.-surgeon, advanced from grade of first lieutenant to that of captain, from March 6, 1906.

Yoss, William E., asst.-surgeon, advanced from grade of first lieutenant to that of captain, from March 6, 1906.

Kieffer, Clas, E., surgeon, sick leave of absence extended twenty days.

Hisham, Wm., asst.-surgeon, ordered to proceed from Fort Logan, Colo., to Fort L. A. Russell, Wyoming, for temporary duty.

Huggins, John B., asst.-surgeon, now at San Francisco, is assigned to duty in the Army Transport Service and will report in person to the medical superintendent of that service at San Francisco.

Mason, George L., dental surgeon, ordered to visit Key West Barracks, Fla., for three weeks; then Fort Morgan, Ala., for three weeks.

Wing, Franklin F., dental surgeon, left Fort Riley, Kansas, for duty at Fort Omaha, Neb.

Shollenberger, James E., contract surgeon, left Fort Brown, Texas, for duty at Fort Ringgold, Texas.

Keefer, Frank R., contract surgeon, left Fort Ringgold, Texas, for duty at Fort Bliss, Texas.

Wall, Francis M., contract surgeon, returned to Fort Oglethorpe, Ga., from leave of absence.

Conroy, John M., contract surgeon, relieved from duty at Fort Trumbull, Conn., and ordered to Fort Terry, N. Y., for duty.

McMillan, Clemens W., contract surgeon, relieved from duty at Fort Terry, N. Y., and ordered to Fort Trumbull, Conn., for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending March 10, 1906:

Plummer, R. W., P. A. surgeon, detached from the Naval Recruiting Station, Kansas City, Mo., and ordered to the Naval Recruiting sub-station, St. Joseph, Mo.

McDonald, W. S., asst.-surgeon, ordered to the *Yankee*.

Schwering, L. H., acting asst.-surgeon, ordered to the *Cette*.

Dennis, J. B., surgeon, detached from the Naval Hospital, Pensacola, Fla., and ordered to the Naval Proving Grounds, Indian Head, Maryland.

Repton, F. L., surgeon, detached from the Naval Hospital, Brooklyn, and ordered to the Naval Hospital, Pensacola, Fla.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending March 7, 1906:

King, W. W., P. A. surgeon, directed to report to the director of the Hygienic Laboratory for temporary duty.

Ward, W. K., asst.-surgeon, granted seven days' leave of absence from March 3, 1906.

Boeder, J. H., acting asst.-surgeon, granted one month's leave of absence, from March 31, 1906, and excused for a further period, April 30 to June 30, 1906, without pay.

Grace, J. G., acting asst.-surgeon, granted leave of absence for one month, from March 29, 1906, and excused from duty without pay April 29 to June 29.

Wethorne, W. O., acting asst.-surgeon, granted four days' extension leave of absence, from February 26.

APPOINTMENTS.

Dr. W. R. Brinckerhoff was appointed director of the Leprosy Investigation Station at Molokai, Territory of Hawaii, February 2.

RESIGNATION.

Mathias Valerius resigned as pharmacist of the second class to take effect March 8, 1906.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended March 9, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, Feb. 17-24, 2 cases; San Francisco, 10 cases.
 District of Columbia: Washington, Feb. 24-March 3, 15 cases.
 Florida: Dade County, Feb. 17-24, 5 cases; Duval County, Feb. 10-24, 27 cases; Escambia County, Feb. 10-17, 1 case; Jackson County, Feb. 10-24, 15 cases, 1 death; Orange County, Feb. 17-24, 4 cases; Polk County, Feb. 10-24, 11 cases.
 Georgia: Augusta, Feb. 19-March 5, 9 cases.
 Illinois: Chicago, Feb. 24-March 3, 1 case.
 Indiana: Terre Haute, Feb. 24-March 3, 1 case.
 Kansas: Leavenworth, Feb. 1-28, 1 case.
 Kentucky: Covington, Feb. 24-March 3, 2 cases.
 Louisiana: New Orleans, Feb. 24-March 3, 4 cases.
 Maine: Biddeford, Feb. 24-March 3, 1 case; Portland, 1 case.
 Maryland: Baltimore, Feb. 24-March 3, 2 cases.
 Missouri: St. Louis, Feb. 1-31, 17 cases.
 Montana: Helena, Feb. 1-28, 1 case.
 Ohio: Canton, Feb. 17-24, 1 case; Cincinnati, Feb. 23-March 2, 8 cases.
 Tennessee: Nashville, Feb. 24-March 3, 2 cases.
 Utah: General, Jan. 1-31, 122 cases; Ogden, Jan. 1-31, 6 cases; Feb. 1-28, 4 cases; Salt Lake City, Feb. 17-24, 25 cases.
 Virginia: Roanoke, Feb. 1-28, 5 cases.
 Washington: General, Jan. 1-31, 2 cases.
 Wisconsin: Appleton, Feb. 24-March 3, 2 cases; Beloit, 2 cases.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Jan. 15-31, 36 cases.
 Canada: Queen's County, March 1, 2 cases; St. John, 1 case; Toronto, Feb. 17-24, 2 cases.
 Gibraltar: Feb. 18-25, 12 cases.
 Great Britain: Bristol, Feb. 10-17, 4 cases; London, 2 cases.
 India: Bombay, Jan. 31-Feb. 6, 3 deaths; Calcutta, Jan. 20-27, 102 deaths; Karachi, Jan. 28-Feb. 4, 12 cases, 4 deaths; Madras, Jan. 27-Feb. 2, 27 deaths; Rangoon, Jan. 20-27, 46 deaths.
 Mexico: Tuxpan, Feb. 10-27, 4 deaths.
 Turkey: Alexandretta, Feb. 3-10, 20 cases, 2 deaths.

YELLOW FEVER—FOREIGN.

Mexico: Vera Cruz, Feb. 11-17, 1 case.
 Panama: Bocas del Toro, Feb. 22, 1 case.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 20-27, 44 deaths; Rangoon, 4 deaths.

PLAGUE—FOREIGN.

Brazil: Pernambuco, Jan. 15-31, 1 death.
 India: General, Jan. 20-27, 4514 cases, 3,747 deaths; Bombay, Jan. 31-Feb. 6, 81 deaths; Calcutta, Jan. 20-27, 30 deaths; Karachi, Jan. 28-Feb. 4, 16 cases, 14 deaths; Madras, Jan. 27-Feb. 2, 12 deaths; Rangoon, Jan. 20-27, 33 deaths.
 Japan: Formosa, Jan. 1-31, 48 cases, 38 deaths.
 Peru: Chocisca, Jan. 21-31, 2 cases, 1 death; Lima, 3 cases, 1 death; Mollendo, 2 cases, 3 deaths; Trujillo, 14 cases, 5 deaths.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5-8.

Association of American Medical Colleges, Pittsburgh, Pa., March 19.
 Medical Association of the District of Columbia, Washington, April 3.
 Tennessee State Medical Association, Memphis, April 10.
 Medical Association of the State of Alabama, Birmingham, April 17.
 Medical Society of the State of California, San Francisco, April 17-19.
 Florida Medical Association, Gainesville, April 18.
 Medical Association of Georgia, Augusta, April 18.
 Mississippi State Medical Association, Jackson, April 18.
 South Carolina Medical Association, Columbia, April 18.
 State Medical Association of Texas, Fort Worth, April 24-26.
 Arizona Medical Association, Phoenix, April 24-25.
 Medical and Chirurgical Faculty of Maryland, Baltimore, April 24-26.

AMERICAN LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL SOCIETY.

Meeting of the Middle Section, held in Chicago, Feb. 24, 1906.

DR. WILLIAM L. BALLENGER, Chicago, in the Chair.

Bullet Wound of Mastoid; Operation; Recovery.

DR. JAMES E. LOGAN, Kansas City, Mo., cited the case of a man, 48 years of age, who was shot in the right ear on Christ-mas day, 1896. The bullet, 38-caliber, passed through the fleshy portion of the right shoulder and entered the external meatus, lodging in the middle floor of the ear. Facial paralysis on the right side followed immediately. An operation was performed at once for the removal of the bullet, but without success. The middle ear began to suppurate while the patient was still in the hospital. The discharge stopped after six weeks. These attacks of suppuration came on at intervals, followed by periods of cessation, until 1902, after which time the suppurative process continued without interruption. Pain at times was very severe in the region of the ear and on the top of the head, but there were no other symptoms referable to the head, except the constant facial paralysis.

The man was operated on July 6, 1905, by Dr. Bisby, who was unable to locate the bullet. The suppuration process continued with increasing activity, and the patient was sent to Dr. Logan, Dec. 11, 1905. There was very little pain; temperature, 99.2 F.; pulse, 80; tongue coated. The tissues covering the mastoid and extending over the occiput were highly inflamed and a fistulous opening existed just beneath the lobe of the ear, allowing some of the discharge to pass through this channel. Much necrosis was evident, which accounted for the terrible odor emitted from the wound. On September 18 the mastoid was opened just back of the auricle and after thoroughly opening up the infected area and enlarging the meatus, the bullet was located in the floor of the middle ear. Extensive necrosis had taken place, so that all of the anatomic outlines were destroyed. The facial nerve had been severed and the bony roof of the antrum was absent, exposing a part of the dura. Necrosis of the external plate extended as far back as the emissary vein. Dead bone was removed wherever found. A noticeable feature was the excessive hemorrhage that occurred during the operation.

The wound was treated as in an ordinary radical operation. The horizontal incision was sutured and three stitches were taken in the upper portion of the post-auricular incision, the lower portion being left open. The cavity was thoroughly packed with iodoform gauze and the usual external dressing was applied. The patient made a rapid and uneventful recovery.

Anesthesia in Tonsil and Adenoid Operations.

DR. L. C. CLINE, Indianapolis, Ind., suggested the following points for discussion: 1. Is it necessary to use a general anesthetic in all or in the majority of operations for adenoids and tonsils? 2. If so, what is to be the choice of an anesthetic? 3. Can not these operations be done just as efficiently, with less shock and danger to life and postoperative complications, without a general anesthetic?

The author believes that in the majority of cases it is possible to do as clean and as thorough an operation with a local as well as with a general anesthetic. It is his custom to have two assistants. One takes the child on the lap or on the right knee, leaning forward against the patient's shoulder, grasping the body, holding arms of patient at sides, and feet off the floor, if possible. The second assistant grasps the top of the head over the right shoulder of the first assistant to hold the patient firmly. A tongue depressor is passed over the tongue, touching the pharyngeal wall, when the mouth will at once come wide open; the forceps or curette is then placed in position behind the palate. The tongue depressor is now withdrawn partially, if not completely, so that there is no obstruction to breathing. The majority of children, if held firmly in this position, will struggle but little. The curette is passed high up in the vault and moved about until the mass of the tonsil or adenoid is felt to be grasped. A firm sweep with a little rocking motion will remove the mass. A second and third sweep on the sides will complete the work. If forceps are used he usually finishes with the curette.

DISCUSSION.

DR. M. A. GOLDSTEIN, St. Louis, is a firm advocate of the quicker and simpler forms of anesthesia for removing adenoids and tonsils, such as nitrous oxid gas, etc. He does not consider that either the operation for adenoids or for the removal of the faucial tonsil has a sufficiently lengthy technic to place a patient under a general anesthetic. There is a certain amount of risk attending the use of a general anesthetic in these cases.

DR. JOS. C. BECK, Chicago, considers ether the safest general anesthetic for the removal of tonsils and adenoids, particularly where the operator has to dissect out tonsils in children. In adults cocaine and adrenal preparations can be used.

DR. EDWIN PYNCHON, Chicago, said the selection of the anesthetic depends entirely on the age of the patient and the condition of the tonsils. In children, who can be held, and in whom the tonsils protrude, the patient should be held firm and rigid, so that the operator can go ahead and remove the tonsils. If the tonsil is buried and has to be removed by being dissected out carefully, a general anesthetic is necessary.

where a local anesthetic can be used he is in favor of it. He has used local anesthesia in children as young as 6 years for cautory dissection operations. For children over 13 and for adults he uses local anesthesia whenever possible.

DR. DERRICK C. VAN, Cincinnati, believes in giving a general anesthetic for these operations, because most of them are major procedures and should, if possible, be done in hospitals.

DR. H. W. LOEB, St. Louis, indorsed what the essayist said in reference to the removal of ordinary adenoids and uncomplicated tonsils without general anesthesia. After an experience of ten years in the use of chloroform he has practically discarded it except in cases requiring careful dissection of the tonsils in young children.

DR. JOHN F. BARNHILL, Indianapolis, said that in the average case adenoids can be removed so simply and quickly, and painlessly, under local anesthesia, we are not justified in giving a general anesthetic. However, the personal equation is an important factor.

DR. GEORGE F. KEIPER, Lafayette, Ind., has never found it necessary to have complete anesthesia for the removal of tonsils or adenoids, because when there is complete general anesthesia the danger from the anesthetic itself is greatly increased.

DR. WILBUR W. BULLETTE, Pueblo, Colo., reported the death of a child, 5 years of age, from general anesthesia for the removal of adenoids and tonsils, and since then he has been a little chary in using a general anesthetic for these operations.

Indications for the Submucous Resection of the Nasal Septum.

DR. ROBERT LEVY, Denver, said that a condition which is very commonly responsible for difficult nasal respiration, reflex disturbances or naso-pharyngeal discharge, is the presence of exostoses and enchondroses from the septum. These are nearly always associated with more or less deflection, and it is frequently difficult to determine whether a large spur or ledge alone is sufficient to produce the symptoms, or whether the deflection is sufficient to materially increase the difficulty. In deciding on the treatment and the character of the operation indicated, one must not only determine the nature of the difficulty to be overcome, but must also consider the effect on the patient. Operations should be chosen, all things being equal, with a view to simplicity; the shorter the operation, the less shock and discomfort to the patient.

The window resection presents the ideal method for the correction of certain deformities of the septum. It has none of the elements of mutilation that other operations have, nor is it the simple incision of a structure which so frequently characterizes rhinological operations. A contraindication to all operations on the nasal septum is the existence of syphilis, either hereditary or acquired. He does not wish to detract from the importance and immense value that the submucous resection of the nasal septum offers. It is the most ideal operation for deflected septum. It is, however, an operation requiring a decided perfection of manual dexterity and perfect technic; it also requires more endurance and consequently produces more shock; therefore, before deciding on its performance, the symptoms should be weighed carefully and judgment exercised, so that it can not be charged against rhinologists that they operate because of some simple anatomic abnormality rather than because of definite disturbing symptoms.

Evils of Mouth-Breathing.

DR. C. P. LINHART, Columbus, Ohio, said that in trying to find the origin of many cases of chronic pharyngitis his suspicions were attracted to mouth-breathing as one of the common causes of this complaint. It is only in later childhood, subsequent to hypertrophy of the adenoid tissue in the vault of the pharynx and hypertrophy of the tonsils, that children begin to breathe through the mouth. Children are often housed in overheated and ill-ventilated rooms, and coddled in heavier wraps than are necessary for their health. These bothouse surroundings ill prepare them for the vigorous and sudden changes that they undergo in passing from warm rooms into the winter air. One of the probable evils of mouth-breathing in early life is the raising of the palatine arch by undue pressure from the inhalation of air through the mouth.

This excessive arching of the hard palate, which is also the floor of the nose, encroaches on the space in the nose. During development the septum naturally grows so as to fill the space allotted to it in the nose. That space is consequently narrowed in its perpendicular diameter, and it naturally follows that the septum will bend to one side or the other. When a person has a high arched palate one may expect either to find a deflected septum in the shape of a large curve, or a sharp kink or spur. The latter is nearly always seen along the line where the vomer joins the perpendicular plate of the ethmoid. There is no doubt that mouth-breathing, with its consequent high arching of the palate, is responsible for the peculiar shaping of the face seen in many children suffering from adenoids. It is also a factor in causing the protruding and misshapen teeth of the upper jaw.

Any obstructions should be removed by surgical means and the patient encouraged to breathe through the nose. Even later in life, when the bones of the mouth and nose are completely ossified, the openings of the nares can be enlarged by proper breathing exercises. The following axioms are recommended for keeping the nose in a normal condition: Cool living rooms; well ventilated sleeping rooms; cold bath, especially for the neck and spine; dry clothing; simple foods; regular habits; moderate daily exercise, and always breathe through the nose.

Treatment of Hypertrophic and Intumescent Rhinitis.

DRS. E. FLETCHER INGALS and STANTON A. FRIEDBERG, Chicago, drew the following conclusions: 1. The galvano-cautery, when properly used, offers one of the best, if not the best, methods for the treatment of the intumescent and hypertrophic forms of rhinitis. 2. The dangers of middle ear infection have been greatly exaggerated, not any case in the series, and only one among several thousand cauterizations, having come under their observation. 3. The liability to adhesion formation is not great, providing sufficient care is taken not to injure the opposite septal mucous membrane; and providing in cases in which the subsequent swelling is marked a probe be passed between the opposing surfaces in four or five days. 4. A 4 per cent. solution of cocaine, according to the formula published, is sufficient in the vast majority of cases to induce complete local anesthesia, three to six applications on a cotton-wound flat applicator being sufficient for this purpose. As a result of experience, especially in cases of marked intumescence, they believe that a spray of adrenalin or suprarenalin, grain $\frac{1}{4}$ to the ounce, materially assists in producing anesthesia. 5. The objection that the galvano-cautery destroys too much of the mucous membrane does not obtain, if the cauterization is linear, and if it is done properly, whereby very little mucous membrane is destroyed. 6. Scab and crust formation does not occur any oftener following cauterization than after other nasal operations. In fact, it was noted in but very few instances, and in some of these a change in the spray solution caused a cessation of this trouble. 7. No packing is needed to prevent hemorrhage, and this factor makes the discomfort following the operation very much less than after some other methods. 8. There is very little pain after galvano-cauterization of the turbinated bodies.

Instruments were exhibited and cases presented by Drs. Frank Allport, Joseph C. Beck, William L. Ballenger and Norval H. Pierce, Chicago; H. W. Loeb and Max A. Goldstein, St. Louis; W. R. Dabney, Marietta, Ohio, and John J. Kyle, Indianapolis.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting held Jan. 20, 1906.

The President, DR. P. K. BROWN, in the Chair.

Atheroma of the Aorta.

DR. WILLIAM OPHITZ showed specimens of atheromatous aorta which had been injected at blood pressure with paraffin. Contrary to Thoma's contention, these showed no bulging of the muscle beneath the atheromatous plaques. Since they were taken from an early stage in the disease, they showed very clearly that the thickening of the intima is not caused by any

primary weakening of the muscularis. The newer histologic methods favor the view that arteriosclerosis is an inflammatory condition.

Genu Recurvatum.

DR. H. M. SHERMAN showed a boy, 15 years old, who suffered from an extreme genu recurvatum. As an infant he had had a spinal kyphosis that had been cured by a plaster jacket. A little later he developed a tuberculosis of the left knee joint. At 8 years an erosion of the joint was done, and two later operations were performed on the knee, in one of which the external popliteal nerve was cut. The deformity of the knee is extreme and is increasing. The boy suffers pain after walking a few blocks. Dr. Sherman stated that in his own experience erosion of the knee joint is practically always followed by a tendency to flexion, which latter takes place even though the joint is in splints. This flexion proceeds to about 35 degrees and then stops. It is much less likely to take place if the continuity of the extensor tissues over the front of the joint is preserved. The patient exhibited extension instead of flexion.

Hydrocyanic Acid Poisoning.

DR. T. C. McCLEAVE reported a series of cases of hydrocyanic acid poisoning that resulted from an attempt to exterminate roaches in a lodging-house. The poisonous fumes diffused to distant parts of the house, especially through an open clothes-chute. The patient most severely affected stated that after noticing the odor of the gas she felt nauseated and dizzy and then vomited profusely. After a brief period of fullness and whirling in the head she became unconscious. When discovered, shortly afterward, she was extremely cyanotic, the mucous membranes were injected and the muscles rigid. Urine was voided involuntarily. She remained unconscious for about eight hours. She was given artificial respiration, oxygen and the usual cardiac and respiratory stimulants. The use of an adrenal preparation seemed to favor recovery more than anything else did. Headache, nausea and vomiting persisted for some days. The cyanosis also lasted for some days and seemed to be dependent on changes in the blood itself. All those who had assisted in removing this patient from the room were more or less affected, being prostrated with headache, vertigo, nausea and vomiting. The blood examination of one of these showed 4,000,000 red cells, 9,000 leucocytes and a normal differential count. The urine was scant and smoky, but showed no albumin.

DR. RIXFORD spoke of the value of suprarenal preparations in surgical shock. He has seen the blood pressure rise markedly after injections of this substance, and in one case in which strychnin and salt solution had been previously administered he felt confident that the adrenal solution had saved the patient's life.

Operations on Thyroid.

DR. W. I. TERRY reported a series of nine operations on the thyroid gland, with no deaths. Eight of these patients had more or less severe symptoms of exophthalmic goiter and all were improved as a result of the operation. In several the x-ray and the serum treatments had been tried previously without success. In all the right lobe was much larger than the left. The operation was essentially that elaborated by Kocher. A local anesthesia was employed. In one patient, while tying the inferior thyroid artery the voice suddenly became squeaky, and it only needed a readjustment of the ligature to free the nerve which, as not itself seen. The collar incision was preferred because it gives a better exposure of the gland and because it leaves a better cosmetic result. The individual vessels were isolated and tied. As a rule the stump of the gland was cauterized with carbolic acid and a small drain was left in for twenty-four hours.

Paroxysmal Tachycardia Associated with Exophthalmic Goiter.

DR. P. K. BROWN reported in detail the case of one of the patients operated on by Dr. Terry. A woman, 41 years old, gave a history of paroxysmal tachycardia since she was 12 years old. One of her children also has these attacks. She was observed in several paroxysms of tachycardia, during which her pulse rate reached 280 per minute. Gradually a small goiter developed, associated with tremor, general nervousness, pigmentation of the skin and marked general weakness. Over a period of two years she was treated with various medical remedies, in-

cluding two kinds of dried serum from thyroidectomized animals and the x-ray, but without any other effect could be accounted for by the rest in bed. After a part of the gland was removed she improved immediately and considerably.

DISCUSSION.

DR. CHENEY said that many cases of exophthalmic goiter seem to run a self-limited course, and if the symptoms can be relieved the disease will terminate of itself. Others must come to the surgeon, but the operation should be a last resort and should not be performed until medical treatment has been given a fair trial.

DR. S. STILLMAN stated that he has under his charge for other conditions two patients who previously suffered from exophthalmic goiter, with enlargement of the thyroid, rapid pulse and tremor. They both recovered spontaneously. He is not in favor of early operations on comparatively mild cases.

DR. DUDLEY TAIT recently visited Jaboulay's clinic in Lyons and saw some of the results that follow sympathectomy. The exophthalmos and enlargement of the thyroid are nearly always improved. Patients with marked nervous symptoms and those with pronounced tachycardia are not considered favorable subjects for this operation. The operation is comparatively free from danger. The difficulty with local anesthesia in this country is that the people do not realize the dangers of general anesthesia and are not tolerant to pain. For this reason many operators find it necessary to use ether in goiter operations.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Pneumonia.

In an article in the *Medical Review of Reviews*, Dr. Henry P. Loomis gives an account of the treatment followed out by four of the large hospitals of New York. The general outline is as follows: On admission the patient is usually given calomel in small and repeated doses, followed by a saline cathartic. Local applications are usually restricted to those cases in which there is intense pain and distress. As a general rule, however, local applications are not used. In the height of the disease the diet is composed almost exclusively of milk, either plain or modified to suit the individual case. While the treatment of the temperature is not the same in the different institutions, it is regarded that a temperature of 104 F. or even higher is not regarded as a necessary indication for special treatment, unless there is marked nervous manifestation, increased restlessness, or delirium. The temperature may be combated by cold packs applied to the anterior portion of the chest, or by alcohol sponging. Sponging with tepid water at a temperature of from 80 to 85 F. may be employed to reduce temperature. Tub baths are given only in cases of toxicemix pyrexia or in alcoholic cases with marked nervous manifestations. To control the cough, codain is recommended in doses of $\frac{1}{4}$ to $\frac{1}{2}$ grain (.015-.03) each, every four hours. Heroin may occasionally be given in doses of $\frac{1}{12}$ grain each (.005), and in severe cases morphin may be used. Where there is evidence of pulmonary edema, hypodermics of adrenalin are resorted to; also atropin, cupping and stimulation. Insomnia may be a disturbing factor in the course of the disease and may require special treatment.

According to Loomis, oxygen is not so generally given now as formerly. Its use is restricted to those cases complicated by marked dyspnea and cyanosis.

In the treatment of the heart, cardiac stimulants are resorted to when indicated in the different cases. Alcohol, he says, ranks first as a cardiac stimulant; strychnin and digitalis are also used. The latter preparation, however, is not used to the extent that either alcohol or strychnin is employed. Nitroglycerin may be resorted to, according to this author, only occasionally. Saline enemata are of service, especially in

alcoholic cases and in those cases in which nutrition is rapidly failing. Eight ounces of a normal saline solution may be introduced into the bowel through a funnel attached to the end of a catheter. These injections may be repeated once in four hours. If the amount of fluid is limited to 8 ounces it is retained, with marked beneficial results. Loomis, therefore, emphasizes the following important points in the treatment of pneumonia: First, the more general use of morphin hypodermically in the early stages of the invasion of pneumonia, which is the stage in which very many cases present shock to the nervous system from a sudden increased toxemia associated with marked pain almost reaching the pain of pleurisy. [While Dr. Loomis advises the general use of morphin, it should be remembered that this drug locks up the secretion and should be used with great caution.—En.] Second, the amount of alcohol used in the treatment of pneumonia should be very judiciously and cautiously used. Third, the avoidance of promiscuous drugging of patients, which produces more damage than assistance in a greater percentage of cases.

Bronchial Asthma.

In the treatment of bronchial asthma, J. P. Oliver, in the *New York Medical Journal*, states that the successful treatment consists first, in treatment during the paroxysms; second, in treatment during the intervals; third, in proper attention to sanitation and diet. In the treatment of the paroxysms Oliver recommends morphin sulphate hypodermically in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain combined with atropin sulphate in doses of from 1/150 to 1/100 grain, repeated, if necessary, in two or three hours. [In this condition also morphin must be used with care, as there is danger of creating a habit.—En.] If the patient is a neurasthenic, he recommends apomorphin hydrochlorid in doses of from 1/20 to 1/10 grain, and strychnin nitrate, in doses of from 1/60 to 1/40 grain, the latter preparation being used to prevent depression from the effects of the apomorphin. The constitutional treatment consists of the following combination:

R. Potassii iodidi	3ii-vi	8-24
Hydrargyri chloridi corrosivi.....	gr. ss	03
Ammonii chloridi.....	gr. x	65
Liquoris potassii arsenitis.....	3ss	2
Aque dest., q. s. ad to make.....	3iii	90

M. Sig.: From one teaspoonful to a dessertspoonful in a half a glass of water three or four times a day, beginning with the smaller dose, and gradually increasing to the larger dose.

He advises against the use of tobacco in all forms, especially cigarettes. Alcohol should not be used in any form, as it not infrequently tends to provoke severe attacks. The nasal passages and the mouth and throat must be kept in an aseptic condition. The teeth must be carefully cleansed, and if caries are present, they should be properly attended to by the dentist. Flannel should be worn next to the body during the winter and early spring. The sleeping apartment should be well ventilated, especially at night, as the paroxysms not infrequently occur between 2 and 4 o'clock in the morning, consequently all draughts of air should be avoided. Feather beds and pillows for sleeping should not be used. Overeating and late dinners should not be indulged in. F. L. Nelson, in the same periodical, recommends hyoscin hydrobromid given hypodermically in doses of 1/150 grain each, and also adrenalin in doses of from 4 to 8 minims of a 1 to 1,000 solution hypodermically.

In the internal treatment he recommends hot black coffee, belladonna when innervation is disordered, or when there is spasm of the muscular fibers of the bronchi. Chloral hydrate is of service in some cases, given in large doses, but should be used with care.

In the treatment of the nose in severe cases he recommends a spray of a 4 per cent. solution of cocaine in order to rid the passages of the secretions. The administration of this preparation, however, should be carefully guarded by the physician himself. If the patient is weak he should be given iron, quinin, cod-liver oil, phosphorous and nux vomica, as indicated. To relieve the distressing cough Nelson recommends lobelia and ammonium chlorid.

The patient should be instructed to live in the open air, avoiding winds and locations where there are extreme varia-

tions of temperature. Humid atmosphere is bad. The underwear should be of woolen. The functions of the skin and the other excretory organs should be carefully watched; moderate physical exercise is recommended, and the patient is advised to avoid indigestible and fermenting foods, which are liable to result in the formation of gas, in constipation and chemical irritation. Fats and sweets should be limited, starchy foods must be thoroughly cooked and slowly masticated. Among those articles of food which should be avoided are pork, veal, cheese, malt liquors, heavy wines and champagne. The heavy meal should be taken in the middle of the day, the supper should be light in order that gastric digestion may be completed before the patient retires. Water should not be allowed with the meals.

Cold Fresh-Air Treatment of Pneumonia.

W. P. Northrup, in the *Boston Medical and Surgical Journal*, relates a case of a wandering grip pneumonia involving the entire left side, which was combated by what he calls the cold fresh air treatment. In this case he placed the head of the bed between two open sashes in a bay window. The sashes were lowered and left widely open. As this was in March the room temperature was 40 F. The nurses were compelled to wear heavy wraps night and day. The patient had no oilskin jacket and no cover over the chest, and the arms were left out. The boy's respirations ranged from 35 to 40, and the temperature reached from 104 to 105 during the day; the pulse was seldom above 120. Going on the theory that the boy was overheated and prostrated with poison, Northrup adopted this means of treatment. The fresh air moved the hair on the patient's forehead, passing in at one window and out at the other. Muttering delirium, hot dry skin and a dry tongue were the indications for plenty of water and air, consequently the author adopted this method to cool and dilute the blood stream, to aid the system in unloading its toxic material, and to increase the natural drain. He mentions the fact that patients can not catch cold while the fever is present, and states that with this treatment they are more comfortable, bear the disease better, and recover earlier and more perfectly, and with less danger.

Quillaja as an Emulsifying Agent.

According to L. F. Hemmans, in *British Medical Journal*, the value of quillaja as an emulsifying agent is not sufficiently known. The following emulsions are easily prepared and, according to this author, remain permanent on the addition of either alkalies or acids:

To make a chloroform solution:

R. Chloroformi	3iv	36
Tinct. quillaje	3iii	12
Aque	3x	130

M. Ft. emulsio.

Aqua menthae piperitæ:		
R. Olei menth. pip.	3iv	16
Tinct. quillaje	3ii	8
Aque	3x	130

Aqua camphore conc:

R. Pulv. camphore	3i	4
Spiritus rectif.	3iin	12
Dissolve and add		
Tinct. quillaje	3iss	6
Aque	3iii	90

Emulsio ol. santali:

R. Olei santali	3i	4
Tinct. quillaje	3ss	2
Aque	3i	30

Aque	3i	30

Cure of Eczema by Bier's Hyperemia.

Dr. George Richter, St. Louis, in the *St. Louis Medical Review*, February 24, reports the cure of a case of eczema by

Bier's method of congestive hyperemia. The patient was a boy of 16, otherwise healthy, who belonged to a good family, in which absolute cleanliness is insisted on. When he consulted Dr. Richter, Nov. 22, 1905, there were many fresh and a few older papules and crusts on the forehead, both cheeks, upper and lower eyelids, both lips and in the border of the hair near the right ear. The lesions closely resembled those of impetigo contagiosa. A 5 per cent. salicylic acid salve was prescribed, but by November 25 the trouble had extended over a larger surface. Resorcin salve, 2 per cent., was ordered and the patient was sent to a hospital. The itching had lessened and the condition of the skin had improved about the forehead and eyes, but the eczema had extended over the chin and to the right eye, completely closing the latter. The right ear was also involved. By December 2 the left eye was also involved, though the right eye showed a little improvement. Hebra's salve was applied on chamois and a few days later slight improvement was noted, but this consisted really in the clearing up of some places with fresh lesions in others. A 3 per cent. borie salve was then tried. During all this time the salves were applied once a day and the face was gently cleaned by rubbing it with olive oil. On December 16 Dr. Richter decided that no real progress toward recovery had been made and determined to try the congestive hyperemia advocated by Bier in other inflammatory conditions.

He ordered the face covered with plain vaseline and applied a half-inch silk-woven rubber band with a self-locking device round the throat, just tight enough to cause a slight congestion of the face, but without causing the patient any great discomfort. After about twelve hours there was edematous swelling of the eyelids. The itching disappeared, and within forty-eight hours the effect was remarkable. Sleep was uninterrupted. The temperature never rose above 98.4; the slightly coated tongue cleared up; crusts no longer formed; the oozing of serum stopped and the inflamed border of the affected area vanished. Thirteen days after the application of this method of treatment the eczema had disappeared; no trace of a skin affection could be seen.

Medicolegal

Care Required of Surgeon Volunteering Services.

The Supreme Court of the United States says, in the case of the Guardian Trust and Deposit Company vs. Fisher, that an individual may be under no obligation to do a particular thing, and his failure to act creates no liability; but if he voluntarily attempts to act and do the particular thing, he comes under an implied obligation in respect to the manner in which he does it. A surgeon, for instance, may be under no obligation, in the absence of contract, to assume the treatment of an injured person, but if he does undertake such treatment he assumes likewise the duty of reasonable care in such treatment.

Board of Health Diagnosis Conclusive.

The Court of Appeals of Kentucky holds, in the case of the City of Bardston vs. Nelson County, an action brought to recover the expenses of a quarantine against smallpox, that the jury should have been instructed that the action of the board of health in diagnosing the case of a person sick and declaring him ill of smallpox, and in directing the quarantine to be established by the city, was conclusive as to it and the fiscal court of the county, and should be so regarded by the jury in arriving at a verdict. Furthermore, the court holds that the trial court should have sustained an objection to and a motion to exclude the testimony of certain witnesses that the man did not have the smallpox, when the witnesses were not and did not claim to be experts and were not familiar with the disease or experienced in its treatment. The prejudicial effect of this testimony, the court says, was not lessened by an admonition to the jury that it might be considered by them in determining the reasonableness of the city's charges for the articles furnished and services rendered by it in preventing the spread of the smallpox. The court is unable to see that this testimony was any more competent for the purpose the jury were told to consider it than it would have been on the question of whether or not the man had the smallpox.

Not Waiver of Right to Object to Disclosures.

The Supreme Court of Indiana says that, in Indianapolis & Martinsville Rapid Transit Co. vs. Hall, a personal injury case brought by the latter party, the plaintiff and his daughter testified to his condition after his injury. While so testifying they stated that the plaintiff made complaint of certain pains to the attending physicians, and also incidentally testified to declarations claimed to have been made by such physicians, while treating the plaintiff, as to the nature and probable result of his injury. Counsel for the company contended that the disclosures by the plaintiff and his daughter, testifying on his behalf, as to his condition and the circumstances attending the visits of the physicians, should have been accounted a waiver of the right to object to said physicians as disqualified, or, in other words, it was claimed that the company was at liberty to examine said professional witnesses generally; and it was particularly contended that they were competent for the purpose of denying or explaining the statements attributed to them. But the court holds that there was no general waiver on the part of the plaintiff of the right to object to the physicians as witnesses for the company. It says further that there were many matters within the company's offer to prove by the physicians concerning which they remained wholly incompetent. The question as to the competency of the physicians as witnesses to explain or deny the statements attributed to them was not presented. It was only in the course of an offer to prove that there was a tender of any such evidence. It is a settled rule of practice that there must be a question asked which is calculated to elicit the testimony excluded to present any question concerning the ruling. Moreover, it is the duty of a party to select the competent from the incompetent in offering testimony, and he can not impose this duty on the trial court. It is too much to expect that a court, without even the aid of an opposite question, shall sift out of a long offer to prove, consisting largely of that which is incompetent, an item of proposed testimony which would only be admissible because of certain testimony which had been previously offered by the other side. The sustaining of an objection to the question in such circumstances is not error.

Construction of Health Policy as to Blood Poisoning.

The Supreme Court of North Carolina says, in the case of Jones vs. Pennsylvania Casualty Company, that the plaintiff, a holder of a health policy, received a small scratch on the hand, which began to inflame, blood poisoning developed and the arm was of necessity amputated. The policy contained a definite stipulation for indemnity in case of disability arising from certain specified diseases, blood poisoning being one expressly named. But, having given this assurance of indemnity, from which, this disease being evidently the direct and controlling cause of the disability, as a matter of first impression the right of the plaintiff to recover would seem to be clear, the policy then took up the matter of provisos by way of restriction, and stipulated further: 1. That the policy should not apply to any illness or disease whatever except those named. 2. That it should not apply to any disease which was complicated with, or resulted from, any disease not therein named, etc. 3. Nor to any disease or illness which resulted from injury, etc. 4. Nor, in effect, to any disease which developed or resulted from those diseases that were named, etc. There were many other limitations and restrictions in the policy, but those set out were enough to show that, if these provisos could prevail, blood poisoning was entirely withdrawn from the operation of the policy, and any and all stipulation for indemnity concerning it effectually removed. Now, so far as the court is informed, blood poisoning is not considered as one of the primary or idiopathic diseases. It is a toxic condition of the blood, caused either from or through a surface wound or some internal lesion or from the breaking down of tissue incident to an existent or precedent disease, and thereby producing suppuration. As to this disease, therefore, these provisos removed every possible condition where the disease could occur, and if upheld would, as stated, entirely set aside the definite contract for indemnity contained in a former clause of the policy. Such a result could not be permitted and is not sustained by authority. It is established doctrine in construing these policies that doubts shall be resolved in favor of the insured. Another principle applicable

to this case, and equally well established, is that, while clauses in a contract apparently repugnant must be reconciled if it can be done by any reasonable construction, yet a proviso which is utterly repugnant to the body of the contract and irreconcilable with it will be rejected; likewise, a subsequent clause irreconcilable with a former clause and repugnant to the general purpose and intent of the contract will be set aside. The court's conclusion, therefore, is that, as to blood poisoning, the various restrictive provisos in this policy were entirely repugnant to the definite stipulation of indemnity contained in the main body of the contract, where contrary to the general intent and purpose of the policy and could not avail to defeat the plaintiff's recovery of indemnity.

- 5 Splenic Leukemia. H. J. Thompson, La Porte, Ind.
- 6 *Aspiration of the Tympanic Cavity After Paracentesis; a Valuable Aid in the Treatment of Acute Otitis Media. F. Fridenberg, New York.

1. **Epidemic Cerebrospinal Meningitis.**—Leszynsky presents a clinical report and an analysis of the special symptoms in 30 cases representing nearly all types of the disease. The mortality was 50 per cent. Good nursing and proper feeding were the most important features in the treatment. When the weather permitted, the patient was kept in the open air greater part of the day. Hot saline rectal irrigation or hypodermoclysis often proved extremely valuable in improving the patient's vitality. The hot bath, given several times a day, usually allayed excessive irritability and delirium, and temporarily improved the patient's general condition. The ice-bag was applied to the head and neck in every case, but Leszynsky doubts its utility. Whisky, strychnin, digitalis, morphin and ergot were employed when indicated. In several acute cases salicylate of sodium was administered by rectum, but without benefit. Lumbar puncture was performed one or more times in every case, either for diagnostic or therapeutic purposes. It was never followed by unpleasant results. In two of the patients who recovered, lysol solution was injected into the spinal canal. In one instance a 1 per cent. solution was used without apparent effect. In the other a 10 per cent. solution was used, and it seemed to have some influence in hastening recovery. It was also used in several of the fatal cases without benefit.

2. **Heart in Tuberculosis.**—Hutchinson has found, after careful investigation, that a weak, undersized, muscular deficient heart, indicated by a weak, rapid pulse and defective first sound, approaching embryocardia, is one of the most constant and significant conditions present in consumption. This condition, in a considerable percentage of cases, precedes the development of tuberculosis. The earlier in the disease this condition presents itself, and the more striking its degree, the more serious the prognosis. This undersized and inadequate heart is normal at about the period of puberty. Hutchinson urges that the condition of the heart should be the principal guide in the diagnosis, prognosis and treatment of consumption. A persistent rapid pulse, without other ascertainable cause, should always arouse suspicions of incipient tuberculosis.

6. **Aspiration of Tympanic Cavity.**—The procedure described by Fridenberg is the evacuation by section of the tympanic cavity immediately after cutting the drum. For this purpose he uses a small glass bulb about five-eighths of an inch wide, shaped like an olive, with a very blunt tip. The neck of the glass bulb is stuffed with sterile cotton and attached to a short rubber tube after both bulb and tube have been thoroughly boiled. Immediately after the paracentesis is made

the glass bulb is pressed against the external meatus, plugging the canal hermetically. Suction is then applied and gradually increased until there is a flow of fluid from the middle ear and the glass bulb fills more or less. Fridenberg has found the effects of this aspiration strikingly gratifying. There seems to be less pain after the paracentesis than when an incision only is made. The otitic pain is more promptly and lastingly relieved. A second incision of the drum is less often required and drainage is much more free.

7. **Public Health Laboratory.**—Westbrook discusses the function and scope of the public health laboratory, and takes occasion to group laboratory work and laboratory workers in the classes in which the present demands and growth seem to place them.

8. **Cause of Epilepsy.**—Lerch advances the theory that the basis of epilepsy is a diseased brain, congenital or acquired. The widely accepted theory of autointoxication he considers, with the rest of etiologic factors, as a remote cause producing congestion and edema. He thinks that the large number of patients in whom a neuropathic constitution and epilepsy can be traced directly, and the large variety of lesions that are found in the epileptic brain favor the correctness of his theory. He says that the same train of symptoms, occurring under the most varied conditions, in patients of all ages, uninfluenced by sex, climate and disease, calls for one direct cause to produce the attack. This cause is congestion and edema.

9. **Treatment of Chronic Urethritis.**—Ballenger's method consists in the employment of a sound which has been coated with the solidified ointment of Unna, which contains, in addition to silver nitrate and cocoa butter, balsam of Peru and white wax, to harden the ointment after it has been smeared on the sound. To facilitate the hardening of the ointment, the sound is cooled in ice-water. This method of treatment has proved so satisfactory that Ballenger has adopted it as a routine method of applying medicine to the urethral canal in any chronic condition.

The sounds are prepared in the following manner: From 2 to 3 gm. (30 to 45 gr.) of silver nitrate or the medicament desired, is powdered and mixed with 180 gm. (3vi) of melted cocoa butter, which is placed in a tall wide-mouth bottle. It should be sterilized occasionally by boiling in a water bath. When the mixture is to be used it is placed in hot water or on a steam radiator until it liquefies. The largest sound that can be passed easily and another three sizes smaller are sterilized and placed in a pitcher of ice-water. The large sound is lubricated, introduced, and left in place for from three to eight minutes, according to the conditions. The smaller one is dipped into the melted ointment, withdrawn and manipulated for a moment while it cools to obtain a uniform layer, and is then placed in the ice-water. The cold hardens the cocoa butter and the sound may be introduced before this melts, while the canal is cool from the larger sound which is passed first, to prepare the way by overcoming any spasmodic obstruction, and to dilate the stricture, if one exists. The stimulating action of the cold is also desirable. The canal may be irrigated before each treatment. Massage along the urethra can be done painlessly by steadying the sound with the right hand to furnish counter-pressure against the fingers of the left, which devote special attention to the bulb and indurated points. Force of any kind should never be used, nor is the treatment applicable to any acute condition. The intervals between treatments vary from one to four days, according to the reaction which follows and the condition being treated. The strength of the ointment is increased as the urethra becomes more tolerant.

13-14.—See abstract in THE JOURNAL, Jan. 20, 1906, page 220.

15. Photophobia a Nasal Reflex.—Spear contends that photophobia is a nasal reflex. He says that it is a common experience to have a bright light induce sneezing. Hence, there must be a degree of hypersensitiveness of the nasal membranes. When light causes one to blink or to wrinkle the forehead, the nose is at fault rather than the eyes. He says that the so-called hay-fever paroxysms form an exaggerated type of physiologic reflex. These may include all the normal nasal reflexes, lachrymation, sneezing, coughing, hicough, and sometimes vertigo, with nausea and retching. He cites the case of a bellboy who was obliged to await calls in front of a row of electric arc lamps. The young man was unable to endure what had become a source of torture to him without constantly shading his eyes with his hands. Examination showed no defect of vision, but the nose was obstructed throughout the middle fossæ by large hypertrophied turbinals. Direct applications to these swellings produced none of the nasal reflex symptoms. Several weeks of treatment, however, brought about a normal degree of sensitiveness, and as the young man's condition improved, a bright light would bring on a paroxysm of sneezing, the onset of which was delayed longer each time until finally the light ceased to cause reaction.

16. Cancer of the Breast.—Before the radical operations for the removal of a cancerous breast came into vogue, Weir found that in following up the enlarged lymph glands to the very point where the axillary vessels pass under the clavicle, he could often carry his finger under the clavicle to one of the sides of the vessels by pulling the arm vertically upward and thus reach glands, etc., well under and slightly above the clavicle. When no enlarged glands can be felt through the skin of the neck, the little finger or the forefinger can be carried under or beyond the clavicle its full depth into the neck, and the supraclavicular space behind the sternomastoid muscle can be fully explored. If enlarged glands are found in this region Weir makes the customary incision along the edge of the clavicle to the root of the sternomastoid muscle and up a short distance along its posterior border. The space is then cleared of glands and fat tissue. If nothing is found the breast wound is closed and a small cigarette drain is placed in the hole bored alongside the vessels, to be withdrawn at the end of twenty-four or forty-eight hours.

 31 *Medical Support of Nostrums. S. H. Adams, New York.

31. Medical Support of Nostrums.—In discussing this question Adams points out that most patent medicines originate with the medical profession. A physician devises some combination of drugs which he uses with effect, real or imagined, in his practice. The mixture acquires a considerable local fame. Finally it occurs to the doctor that he can make a good thing of that by selling it beyond the little circle of his immediate practice. So he goes to the United States Patent Office and obtains, not a patent, for that would necessitate his giving out the formula, but trade-mark registration. Such is the origin of peruna and many other nostrums. Again, medical testimonials are very easy to get in the so-called ethical field; but they do not seem very impressive when one comes to look into them. The geographical location of the physicians who lend their names to testimonials is interesting, perhaps even significant. Curiously enough, says Mr. Adams, it is just the same class of places that furnishes the familiar "God-bless-peruna" letters which appear in the dailies. If this has any special meaning, it would seem to be that the order of intelligence which prevails in the small town finds similar expression both in the layman and the physician. Foreign testimony from men of standing is much easier to obtain than domestic, because these men, as a rule, are not known in America, nor do they care anything for America.

Adams believes that it might be worth while for physicians in each city to know just which of their fellow practitioners are prostituting themselves to this trade. He suggests that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION might supplement its list of the proprietary associations of America by a list of physicians owned by the proprietary associations. He goes on to say that a vital weakness in the medical opposition to "patent medicines" is the lack of an intelligent idea by the profession of the forces it is fighting. The medical profession is dangerously swift to jump at conclusions. It is fighting a very keen and powerful enemy in the "patent-medicine" man. Its most effective weapon is the truth, and the profession has not found it yet. Through reckless statements it is in danger of forfeiting that public confidence which should be its most potent ally. Mr. Adams says: "Find out where the foe is before you strike. Don't hit out with your eyes shut."

He points out that the greatest present hope is in legislation, and suggests that every medical organization in the country appoint a committee on legislation, made up of its most representative members. The Proprietary Association of America is rent with dissensions. There was never before so brilliant an opportunity for the enemies of fraudulent nostrums. This spring there will be introduced in many state legislatures a patent-medicine bill looking to an effectual guardianship of the public health. Mr. Adams believes that if every physician will stand behind this bill, not alone as a physician, but as a citizen with a vote and a voice for the betterment of his commonwealth, the nostrum business will be so restricted within the bounds of decency and fair dealing that fraud and poison will become unprofitable in those markets. If the medical profession will mobilize its forces and for once speak its mind in the legislative halls, it will result in the effectual crippling of a traffic which takes its profit from suffering and death.

- 32 *Is Syphilis or Mercury Responsible in the Etiology of Dementia Paralytica and Locomotor Ataxia? O. L. Wolter, St. Louis.
 33 Tumors of the Cerebellum. (Concluded.) E. A. Babler, St. Louis.
 34 Treatment of Respiratory Diseases in Children. J. Zahorsky, St. Louis.
 35 Posterior Basal Meningitis. L. M. Warfield, St. Louis.

32. Syphilis or Mercury.—Wolter holds that the theory that paralytic dementia and tabes, in 90 per cent. of all cases, are meta-syphilitic conditions is not so sound as the theory that

the diseases are usually a metamercurial condition. He does not deny that paretics and tabetics are syphilitic, but believes that it is equally true that they have been mercurialized. As the result of considerable study he inclines to the belief that mercury and not syphilis is responsible in the etiology of dementia paralytica and locomotor ataxia. He says that there are important reasons for the belief that syphilis plays a minor rôle in the etiology of sclerosis of the brain and cord. Although the negro is very prone to contract syphilis, paresis and posterior spinal sclerosis are seen rarely in the colored race. The average negro most frequently receives no treatment for lues, and the most severe secondary and tertiary lesions are found in the colored man. Having become a syphilitic, he allows the disease to run a typical course without interference. If he does take mercury it is with no system; it is taken irregularly and for no prolonged period of time. Yet, in spite of all this, he does not become the victim of paresis and tabes. On the other hand, the man of brains, the professional man, the highly educated man, falls a ready victim to paresis. The requisites of thorough anti-syphilitic treatment are brains and money, and, since these are the essentials in obtaining the treatment, Wolter believes that there is the reason why paretics and tabetics are usually individuals of prominence. Wolter also discusses the reasons why paresis takes a long time to develop; how mercury may produce the pathologic changes found in paresis and tabes, and the fact that anti-syphilitic treatment does no good, but actually does harm, pointing out always that the syphilitic etiology of the diseases under discussion appears questionable.

- 30 *Considerations Regarding Prescription Writing To-day. F. M. Corwin, Bayonne, N. J.
- 37 Obstetric Technic in Relation to Subsequent Pelvic Manifestations. J. C. Applegate, Philadelphia.
- 38 Examination of the Eyes and Ears of School Children by School Teachers. L. Emerson, Orange, N. J.

36. Prescription Writing To-day.—Corwin discusses the reasons for the decadence of the old-time prescription and the ascendancy of the prescription calling for proprietaries and "patent medicines." It says that a peep at the shelves and into the closets behind the prescription counters of drug stores reveals a vast array of broken original packages of the wares of the different manufacturing pharmacists, of more or less repute, who have managed, by dint of persistent pushing of literature and samples, to get their preparations prescribed by physicians. Many of these proprietary articles are ethical and many are not. Of those which might in themselves be classed as ethical, some are exploited in a manner which puts them without the class, and makes their use by the medical profession entirely inadvisable.

One of the first and most apparent reasons why physicians prescribe any of these remedies, says Corwin, is that the manufacturing pharmacist can and does turn out a better article than the average retail pharmacist. The combination end concentration of capital, the possession of special apparatus, the employment of skillful chemists, the laboratory facilities for research and experiment, the procuring and handling of crude materials in large quantities, enable the manufacturer of these proprietary articles to turn out a product which shall be as pleasing as possible to the eye, nose and palate. Furthermore, it takes a number of years for a really meritorious formula to find its way into the United States Pharmacopœia, or in other words, to become official. The result is that until a given preparation has been put in the Pharmacopœia, the latter published and in the hands of pharmacists, the mixture obtained in twenty different stores may have been made from almost as many different formulas. Even if each store is provided with the same formula, the conditions behind the prescription counter will readily explain why the products differ. Corwin places much of the blame for the undesirable preponderance and unmistakable attractiveness of these factory-made products on the Pharmacopœia.

Speaking of the objections to prescribing these proprietary articles, Corwin says that the effect on the mind and resourcefulness of the prescriber is detrimental, narrowing, blunting and destructive of individuality, of the ability to adapt a

prescription to the special case before him. The result is that prescription writing is liable to become a lost art. He points out that not only is it the duty of the physician to shun these offending articles, but to do all he can to discourage their use. As soon as one of the monopolized chemicals, under the coined name, becomes recognizable and is put in the market under its chemical cognomen, physicians should take pains to familiarize themselves with the fact, and to make use of the preparation. The use of but one word, and that a coined word, for the name of a remedy is objectionable in that it readily catches the eye, and is in turn learned by patients. The consequences to the latter are likely to be disastrous because, if the remedy works well, especially for the relief of some frequently recurring condition, such as headache, the patient falls a ready prey to the drug.

39. Radical Operation for Cancer of Uterus.—Clark states that while the operative statistics up to this time must dampen the enthusiasm of even the most ardent optimist, on the other hand, they are sufficiently encouraging to cheer even the pessimist if he will only give the study of ultimate results an unprejudiced critical review. He believes that more is lost than is gained in the radical operation when the glands are painstakingly extirpated, and that to remove here and there a palpably large gland will certainly not promote the patient's interest so far as a radical cure is concerned. Of all the various methods of operating employed he still adheres to the abdominal one, removing all possible tissue in the vicinity of the primary site of the growth, and using the cautery rather than the knife. In general, he follows the principles laid down by Wertheim, stopping short, however, with the removal of a considerable cuff of vagina with the uterine, and as much parametrium as possible, not prolonging the operation by a search for glands. He says that when one takes into consideration the fact that there is no regularity of metastatic distribution, that in even the earliest cases metastasis may have occurred, and that when the lower accessible glands are involved, the upper inaccessible glands, with the exception of only 13 per cent., are also involved, little argument is left in favor of the extensive dissection of the glands with the largely added mortality that must necessarily follow this act, from shock, infection and other complications.

42.—This interesting article covers practically the same points as the article by Dr. Doty which appeared in THE JOURNAL, Aug. 26, 1905, page 585.

44. Status of Blood Cryoscopy in Determining Functional Activity of Kidneys.—Experiments have convinced Beer that cryoscopy of the blood gives but little absolutely accurate information as to the present activity of the kidneys. The kidneys, though the most important organs in regulating the molecular concentration and osmotic pressure of the blood, are

not the only organs concerned with this intricate process. An anatomically normal or almost normal kidney may be so disturbed in its functional activity as to appear seriously diseased, being temporarily incapable of excreting its quota of molecules. The concentration of the blood may be normal, equal —56 C., even though the kidneys are functionally inactive and anatomically very badly diseased. The concentration of the blood may be increased to —60 C. or higher even though the second kidney is anatomically normal but is suffering from a functional disturbance produced by nervous reflexes, or by toxins which come to it through the circulation from the other diseased kidney. The concentration of the blood may be markedly increased, even though both kidneys are in good condition.

In bilateral disease if nephrectomy is done with normal concentration the operator may remove in the diseased organ the majority of the functioning tissue of the kidneys and thus bring on uremia and death, because the renal tissue left in the patient is inadequate for the excretory work. The list of patients who have survived a nephrectomy, despite high molecular concentration, —60 C., is steadily growing. Patients with normal freezing point do not necessarily survive the operation and are not in any way insured against subsequent uremia. In a large number of cases high concentration corresponds to bilateral kidney tissue, but as yet it is impossible to decide which cases of high concentration are not of renal origin, and, vice versa, which patients with low concentration are suffering or likely to suffer from renal insufficiency.

49. Myxedema with Ascites.—The interesting points in the case reported by Hertzler were the presence of ascites and of leukoplakic spots on the backs of the hands.

52. Blood of Epileptics.—Onuf and Lograsso undertook the study of the formed elements of the blood with the purpose in view of determining whether there existed any connection between the behavior of the formed elements and the epileptic seizures. Nineteen cases were selected, 8 men and 11 women, all of whom had been without bromids for a period of at least two months preceding the examination, and all of whom were idiopathic cases, so far as could be determined. They found that a leucocytosis may already be present directly before a seizure, and, if so, is then not a purely secondary phenomenon produced by the seizure. Furthermore, a grand-mal seizure need not necessarily be preceded or ushered in by a leucocytosis. These observations teach the important fact that there is no absolute parallelism between seizure and leucocytosis. They also show that the leucocytosis is, in part at least, independent of the seizure.

53. Gunshot Wounds of Abdomen.—In Vaughan's series of 14 cases of gunshot wounds of the abdomen there were 8 cases of wounds of the small intestine, 6 of the large intestine (5 of the colon and 1 of the rectum), 5 of the diaphragm and pleura, 5 of the liver, 2 of the stomach, and 2 of the kidneys. Several patients had a number of wounds in one organ, while in others several organs were wounded. One patient had 11 bullet holes in the intestine, while another had perforation of the liver, stomach and colon. One of the patients was not operated on, 1 was operated on late, and 12 were operated on in from one to twenty-eight hours after the reception of the injury. Nine patients died, a mortality of 64 per cent. In 6 cases the cause of death was hemorrhage, in 1 case peritonitis, in 1 case exhaustion, and in 1 case shock or the anesthetic, or both. Vaughan says that he knows of nothing more which could have been done to save the 6 patients who died from hemorrhage, except to have operated sooner.

54. Amputation of Thigh with Replantation.—Carrel and Guthrie attempt to show that a permanently successful replantation of an amputated thigh is possible. The experiment was performed on a dog. The thigh was amputated at the union of its lower and middle thirds. The limb was removed and enveloped with sterilized moist compresses. After a few minutes the amputated portion of the limb was placed on the operating table close to the remaining stump of the thigh. The continuity of the artery and of the vein were immediately re-established by end-to-end suturing. Absolutely no blood escaped from the vessels at the lines of anastomoses. The

pulsations of the popliteal artery immediately became normal and the femoral vein filled with circulating dark blood. The two ends of the bone were closely approximated and sutured together with silver wire. The sciatic nerve was sutured with silk, and the muscles, aponeurosis and skin with catgut. A gauze and collodion dressing was applied. Afterward the lower portion of the abdomen, the hip, the thigh and the leg were enveloped with cotton and the large plaster-of-Paris bandage.

Twenty-four hours after the operation the animal was in good condition and the replanted foot was very much warmer than the other foot. There was considerable swelling, however, which was thought to be due to the inactivity of the vasomotor nerves. Fifty hours after the operation the dog was killed, the development of gangrene being inevitable. The failure of the operation was due only to a fault of technic. A circular constriction produced by the gauze collodion dressing had stopped the venous circulation. The thigh and the leg were dissected. There was no stenosis of the vessels. The anastomoses were perfect. The cut ends of the muscles had united satisfactorily. The connective tissue of the thigh and of the popliteal region seemed normal, while in the leg and foot below the ring of constriction it was markedly infiltrated and edematous. The veins of the foot and leg were extremely dilated and filled with coagulated blood.

59. Operation for Correction of Prominent Ear.—The ears of the young man whose case is reported by McShane extended at right angles from the head and measured at the distal margin one inch and three-quarters. An elliptical section of integument two inches in length and something more than a half-inch in width was removed from the posterior aspect of the ear. The connective tissue was then carefully dissected away and the perichondrium roughened by the use of a curette. Strong catgut sutures were used in the cartilage in such a manner as to fold it on itself. The needle was introduced into the cartilage near the margin of the denuded section and thrust in as deeply as possible, care being taken not to pierce the skin on the anterior surface of the ear. The needle was returned and brought out an inch and a half from the point of insertion. The needle was then carried across the denuded area and a similar hold was taken near the margin of the skin on the opposite side. Four or five of these sutures were introduced, and when they were tied the ear presented the normal anterior ridge in its proper position, the ear was contracted to the normal size and at the same time brought back to the proper distance from the head. Silk sutures were used in bringing the margins of skin together, and the catgut sutures were thus buried. The ears were dressed with antiseptic gauze and cotton compresses and bandaged close to the head so as to relieve the sutures of as much tension as possible. Two weeks later all dressings were removed. The ears are normal in appearance and size.

62. Foudroyant Gangrene.—Two cases of this kind are reported by Wilder. The first patient dropped a pistol from his pocket, and the fall caused the weapon to explode, the ball entering the fleshy part of the calf of the right leg on the inner side, four inches below the knee, passing through the

limb behind the bones which were not injured, and coming out two inches higher on the outer surface. The patient, not believing that his injuries were dangerous, continued to work for two days before seeking medical attention. When first seen the wounds looked healthy, the circulation was good, there was little swelling, but much pain. The leg was dressed antiseptically. The following morning there was more swelling. Hot applications were applied and changed frequently for twenty-four hours, at the end of which time the pain had increased. The pulse was 120, temperature 102 F., and marked gangrene had made its appearance. The thigh was amputated rapidly at the junction of the middle and upper third, but the patient died six hours after the operation, just four days after the injury.

The second patient sustained a compound fracture of the left radius near the wrist. On the fifth day following the injury evidences of sepsis set in about the hand, which was freely incised and dressed in hot bichlorid gauze. During the next twenty-four hours the pulse ran up to 116, and the temperature to 104 F. The skin on the arm began to show a dusky brown color which spread rapidly toward the shoulder, crepitation in the cellular tissues could be felt, and gangrene was evident. Amputation was advised, but was not consented to until four hours later, when the arm was amputated near the shoulder. The stump was left wide open and dressed with hot bichlorid gauze for ten days. After a long and stormy convalescence the patient made a good recovery.

68. Retrodisplacements of Uterus.—Boye insists on the utmost importance of being absolutely familiar with the conditions, pathologic and anatomic, in each individual case. Inasmuch as no one surgical operation is applicable to every case, the surgeon who excludes from his curriculum some of the procedures that are based on principles that do not violate laws of function and pathology, and sees no necessity for anything but shortening round ligaments or ventrosuspension, or what not, will necessarily fail from misapplication. Many cases will need no operation on the uterus for the displacement *per se*; but many times diseased and adherent appendages will demand appropriate treatment. This may be, indeed in a large proportion of cases will be, ablation. The careful observer will find that this procedure, properly executed, has remedied the displacement. Boye warns the pelvic surgeon against the improper application of ligatures in removal of the appendages, to-wit, placing them so as to shorten the posterior surface of the broad ligament or to approximate the distance between the uterine cornua and the sacral promontory.

He suggests that a uterine body very jagged and bleeding on its posterior aspect after separation of adhesions, as a rule, should be removed if the appendages are sacrificed. Future trouble from new adhesions with the subsequent retroversion, endometritis, etc., is so frequently experienced that it may be confidently expected when this rule is violated. When tumors are plainly the cause of retrodisplacement and are removed, due care should be taken to learn whether or not this operation does not entirely remedy the condition. Usually it will do so, and in such an event nothing further should be done. A floating spleen should be removed, a stomach that mechanically acts as an etiologic factor should receive appropriate treatment, as should a lacerated cervix, endometritis, injuries

to the pelvic fascia, subinvolution and cervical hypertrophy in any diameter. The sound principles to employ as guides are, principally, address study and treatment to the existing abnormalities, whether of a congenital or an acquired variety, and to regard the displacement as of secondary importance.

69. Prophylaxis in Abdominal Sections. McKay emphasizes the importance of prophylactic measures in cases of abdominal sections. He believes that the good results obtained by operators are attributable entirely to the careful preparation of the patient before operation.

70. Fibroma Molluscum Gravidarum.—Brickner describes this condition as a lesion of the skin appearing in the latter half of pregnancy, bearing the histologic characters of fibroma molluscum, but differing from it clinically in its total disappearance postpartum at a time when the other regenerative processes are being completed. Its distribution is limited to the neck, the breasts and the submammary area. The lesions are frequently pigmented, but this is not always the case and is not an essential element of the condition. The pigment runs from a light yellowish brown to a dark brown. The disease forms a clinical entity, hitherto undescribed, whose essential elements are the appearance of fibrous mollusca during pregnancy and their disappearance postpartum. Pathologically the group belongs to the group of fibrous mollusca.

83. How Physicians Encourage the Use of Patent Medicines.—A too great indifference to patients' complaints is mentioned by Graham as one of the many ways in which physicians encourage the use of patent medicines. Even though the symptoms are purely imaginary, the physician should give them careful attention so that the patient will not be gobbled up by the luring advertisements of some patent medicine which gives him relief from his imaginary condition. There is another habit that many physicians have formed, and that is using too many stock formulas. Their use begets the habit of prescribing by routine, and although many of these compounds are good, they will not suit every case for which they are recommended. Then there is the habit of prescribing proprietary medicines. These relieve the patient but do not cure him. By studying each individual case carefully and treating it as indicated, Graham says that these evils can be overcome.

3. Acute Abdominal Disorders.—Moynihan discusses the differential diagnosis between acute intestinal obstruction and other conditions which closely simulate this affection in their symptomatology and which often are mistaken for obstruction. The affections discussed in this connection are biliary or renal colic, perforation of gastric or duodenal ulcer, rupture of an appendiceal abscess, tuberculous peritonitis, acute hemorrhagic pancreatitis, and embolism or thrombosis of the superior mesenteric vessels. No new points are brought out.

5. Cancer of the Stomach.—Moynihan has operated on 59 patients suffering from cancer of the stomach. Gastroenterostomy was performed 35 times, with 5 fatalities. The anterior operation (with Murphy's button) was done 7 times, with 2 fatalities. The posterior operation (with suture) was done

28 times, with 3 fatalities. Gastrectomy was done 10 times, with 3 fatalities. The complete operation was done once, with one fatality; the partial operation was done 7 times, with one fatality, and the partial operation, with resection of the transverse colon, was done twice, with one fatality. Gastrostomy, for carcinoma at the cardiac end of the stomach, was done 5 times, with no fatality. Jejunostomy was done 3 times, with no fatality. Exploratory laparotomy (operation not necessary or not possible) was done 6 times, with fatality. Of the 30 patients who survived gastroenterostomy, 20 were traced to the time of their death; 6 are alive and well, and of 4 nothing is known. The earliest death among these occurred in the fourteenth week after operation, the latest two years and four months after operation. Of the gastrectomy cases, one patient has lived four and a half years and is quite well and free from recurrence. Four others have survived the operation between two and a half years and five months. The gastrostomy patients lived from five to seventeen months after operation. The jejunostomy patients lived from four and a half to eleven weeks after operation. In all these cases the stomach was so extensively involved that gastroenterostomy was impossible.

6. Treatment of Perforating Typhoid Ulcers.—Greaves reports 3 cases of this condition in which the patients were operated on. Two of the patients recovered completely.

7. Treatment of Diphtheria.—Rhodes believes that the very slightest exense should be sufficient for the diagnosis of diphtheria in a child. Even so slight a sign as dryness or a parched appearance of the external nares in a child who seems poorly nourished is sufficient to indicate, in most cases, that diphtheria toxin is being manufactured, probably in the nasopharynx. He holds that diphtheria antitoxin never does any harm to a child and that it will assist in curing illness due to some disturbance in the throat or nasopharynx, even if that illness is not actually due to diphtheria. The time lost by delay in giving antitoxin in diphtheria is often sufficient to render the chance of recovery very small. Rhodes states that, though many experienced workers in the field of infectious diseases insist that very large doses are much more efficacious than small ones, sufficient stress is not laid on the fact that small doses, even though given late in the disease, will often just turn the scale in favor of the patient, or at least assist the patient to fight the disease and to hold it in check until the child can be taken to a hospital, where more antitoxin can be given. Finally, if every general practitioner would carry a syringe and one phial of antitoxin much more antitoxin would be given before the child is removed to hospital; the necessary delay in getting the antitoxin at present, and the difficulty, sometimes, in obtaining it, especially in country districts, being possible reasons why this treatment is not adopted immediately in all cases.

11. Teratoma of Neck.—The tumor in the case cited by McGregor was a multilocular cystic mass of about the size of a turkey's egg and of an irregularly conical shape. It contained both mesoblastic and epiblastic elements, so that it probably originated from an abnormal development of one or more of the branchial arches of the embryo. Some of the cysts were lined with a single layer of cuboidal or round cells, while others appeared to have several layers of cells. Some of the cysts had the characters of a dilated gland duct, and gave an

adenomatous appearance to the tumor section. The intercystic part of the tumor contained cartilage, spindle-celled connective tissue, non-striated muscle, arteries, veins and capillaries.

12. **Persistent Aberrant Thymus.**—Sharp's patient, a woman, aged 24, sought advice about a swelling in her neck, which had first been noticed when she was 11 years old, at which time constitutional treatment was tried to reduce it. It had gradually grown larger and had given rise to a marked swelling, situated at the base of the neck on the left side and extending from beneath the posterior border of the trapezius and also passing behind the clavicle. The growth, which was of about the size of an ordinary potato, had the structure of a lobulated gland with a capsule and intersections of fibrous tissue. On section it was found to consist of a mass of leucocytes, containing in their midst numbers of Hassall's concentric corpuscles of various sizes, some invaded by the leucocytes. The growth was divided by fibrous intersections, of which the larger contained fair-sized blood vessels.

13. **Saccular Dilatation of Small Intestine.**—Cautley describes a remarkable anomaly of development in a female infant who died at the age five weeks. She was admitted to the hospital with a history of vomiting since the third day of life. This had steadily persisted, and after the seventh day had been associated with diarrhea. The vomiting followed every meal. The abdomen was unduly prominent on the right side and a tumor of about the size of a pullet's egg could be felt to the right of and on a level with the umbilicus. The tumor was fairly movable, elastic, sometimes dull and at others resonant on percussion, and it would disappear entirely after moderate gentle manipulation. The liver dullness in front was completely absent. An inguinal hernia was present on the left side. The patient took food well, the vomiting ceased and the stools became almost normal. Later vomiting began again, but it stopped after two doses of cocaine and a return to the diet of whey. Finally she became very feeble and cold and died from ashenia. There was no return of vomiting or diarrhea.

On opening the abdomen a cyst with opaque walls was seen immediately below the liver. The transverse colon was pushed downward and the liver upward, so that the edge of the latter was not visible, thus counting for the absence of liver dullness anteriorly during life. The cyst was considerably larger than the stomach, which was of normal size. The cyst measured three inches vertically, two inches transversely and one inch in the anteroposterior diameter. It was situated in the mesentery, arising from the gut at a distance of fifteen inches from the pylorus. It communicated with the gut by two adjacent openings close together; the larger one was slightly smaller than a dime and the smaller one was quite minute. The edges of the openings were smooth and irregular. In general appearance the cyst was similar to a saccular aneurism of the aorta with a small orifice. The duodenum and a small part of the jejunum above the origin of the cyst were much dilated and hypertrophied, while, below, the intestine was thin-walled and collapsed. Opposite the cyst the lumen of the canal seemed somewhat narrowed from pressure, but there was no true stricture. Both cyst and intestines contained normal bile-stained contents. Microscopically, the wall of the cyst was identical with that of the intestine from which it arose, the muscular tissue being considerably hypertrophied.

17. **Removal of Carcinoma of Colon.**—In a case of carcinoma of the ascending colon, about three inches beyond the cecum, Bird operated according to a method devised by him. The tumor is located and, its removal being decided on, the transverse colon is pulled down, two forceps are applied to it close together, a heavy one on the proximal side, and the gut is divided with large scissors in one cut. Swabs are used to avoid soiling the cavity, and the heavy forceps attached to the gut is allowed to hang out of the wound, a proceeding which puts the mesocolon on the stretch. The branches of the middle colic artery and the right colic artery are tied far back by a single ligature, which devascularizes a large portion of mesocolon, which can be severed by large scissors. Forceps are then placed on the ileum, about four inches from the junction of the large and small intestines, and the gut is divided; the distal end now depends from the wound, so that the whole portion to be resected is hanging by the ileocolic artery and some peritoneum.

This blood vessel is ligated far back, the isthmus of tissue left is divided close to it, and the resected gut, two forceps and the ileocolic glands fall out of the wound after some time. There is no need to investigate the important ileocolic lymphatic area, for it has gone, but the mesocolic region should be examined for glands which may have escaped the section.

Thus four, or at most five, arteries have to be tied; the transverse colon is divided at right angles to its lumen, but the ileum, if it approaches the caliber of the colon closely enough to allow of apposition, is severed in a direction obliquely downward to the mesenteric attachment, which, of course, increases the size of the open end. If the disproportion be too great, the ileum is also separated at right angles, the patent lumen to be afterward applied, by means of temporary sutures, to an incision, proportionate in length, in the fundus of the colon about two inches from the gaping end, through which the stay ligatures are pulled, reversing Maunsell's method. The new ileocolic junction is quickly made by through-and-through sutures, to be reinforced after the ileum is pulled back by a continuous Lembert suture.

- 19 Double Lip (Atripthy) of Labial Glands. G. H. Edington.
- 20 *Case of Exophthalmic Goiter in a Man Treated Successfully. W. F. Somerville.
- 21 Roentgen Rays in the Diagnosis of Urinary Calculus. J. R. Riddell.

20. **Treatment of Exophthalmic Goiter.**—The treatment adopted in the case reported by Somerville was isolation, with, at first, complete rest in bed. The windows of the large bedroom were wide open night and day. The patient, a man, was placed on a very liberal diet. In addition to three "square" meals, of which he partook largely, he had soup twice, a large afternoon tea and eighty ounces of milk per diem. He was twice daily treated by the high-frequency currents and every second day five mps. were applied by the continuous current for ten minutes, the positive pole being placed over the thyroid, the negative at the back of the neck. The patient had, further, heart massage each day, i.e., gentle stroking over the precordial region by a skilled masseuse. During the last two weeks he was permitted to go out, when the weather was fine, for a short walk on level ground. The medicinal treatment consisted in the use of the thyrotoxin, which was replaced later by strophanthus, 2 minims every four hours, and thymus gland, 5 grains thrice daily. Later, dram doses, three times a day, of syrup of hydriodic acid were commenced and continued to the end. Smoking was at first prohibited, but later one cigar a day was allowed; no alcohol was administered, but the patient had *café au lait* twice a day and tea once. All the symptoms show signs of improvement, with the exception of the rate of the pulse, which remains from 87 to 95 a minute. Somerville attributes this return of tachycardia to the want of the high-frequency currents, which have an inhibitory influence on the heart's action.

- 22 Diagnosis and Treatment of a Perforated Gastric Ulcer. A. R. Parsons.
- 23 *Treatment of Gastric Vomiting with Oxalate of Cerium. C. A. Sweetnam.

23. **Cerium Oxalate in Vomiting.**—Within the last few months Sweetnam has been using cerium oxalate largely in cases of vomiting due directly to gastric disease, usually giving six-grain doses three times a day in adult patients, combined with ten-grain doses of carbonate of bismuth. In almost every case the result has been most satisfactory, and in several instances, when bismuth alone has failed to cause any marked improvement, a rapid change for the better has appeared when cerium oxalate has been added to the medicine. In gastric ulcer the pain is relieved and the vomiting ceases almost immediately; the same result occurs in chronic catarrhal gastritis, especially the form which is so common among badly nourished young women, whose work deprives them of their proper quantity of fresh air. In cancer of the stomach, although a permanent cure can not be expected, the symptoms are relieved and the patient's life is prolonged and made far more comfortable than by any other means; the pain is lessened, hematemeses ceases and the patients who have been unable to retain the smallest quantity of food taken by the mouth are soon able to retain several pints

of milk per diem and also small quantities of the prepared farinaceous foods. This, of course, does not hold good in cases in which the pyloric region is largely involved and in which the symptoms are mainly due to a mechanical obstruction of that opening.

Presse Médicale, Paris.

24 (XIV, No. 5.) *Le traitement chirurgical de l'anévrisme sous-clavulaire. Savariaud.

25 *La migraine des artériques. P. Hartenberg.

26 *Traitement des ulcères variqueux par l'incision circonférentielle de la jambe. Hårdouin.

24. **Surgical Treatment of Aneurism of Subclavian Artery.**—Savariaud calls attention to the advantages of making more than one incision, thus obtaining better oversight of the field; also to the fine results from the use of the ligature in the case reported, notwithstanding the dilated and weakened condition of the artery; also to the advantage of hollowing out a tunnel underneath the clavicle instead of resecting it, thus refraining from impairment of function later. Another point which he emphasizes is that the presence of coagula does not necessarily imply healing or even a tendency in that direction, as he has frequently had occasion to observe in the clinic and in the cadaver. The part of the subclavian involved close to the axillary is comparatively free from collaterals, and the branches of the axillary anastomose so frequently that there is no danger of gangrene. Out of 4 cases in which the second part of the subclavian and 9 in which the third part was ligated, only 1 patient died of pulmonary embolism. Ligature of the first part of the artery is much more serious. Resection of the aneurism is more dangerous than mere ligation; 1 patient died out of the 7 on record treated by extirpation. These conclusions apply only to aneurism outside of the scalenus muscle. When the origin of the artery is involved the indications and prognosis are quite different.

25. **"Rheumatic Migraine."**—Hartenberg refers to the headache which occurs as one manifestation of the peculiar diathesis or disposition which predisposes to joint disease. He calls it the "migraine of the arthritic," and is convinced that the pain is the result of compression of the nerve terminals by congested blood vessels. Everything that increases the pressure or the spasm—stooping over, any shock, compression or electric stimulation—increases the pain. The nausea and the photophobia are explained by the disturbances in the circulation through the meninges. All these angiospastic phenomena can be reproduced by irritation of the cervical sympathetic. The pathologic irritation is the result, he thinks, of a rheumatoid infiltration of the muscles, a "rheumatic myositis." When the case is recent the muscles are still elastic and supple, but in cases of long standing hard lumps can be palpated in the muscles. The myositis proceeds by waves, under the influence of fatigue, traction on the muscles, dampness, etc. The ganglia may be indurated and the skin infiltrated and thickened. The superior cervical ganglion is always hypertrophied and tender, and sometimes the inferior and the middle ganglia. This is the true cause of the migraine, which may be regarded as a reflex neurosis, similar to certain forms of reflex epilepsy. He has been very successful with treatment based on these assumptions; sodium salicylate is applied directly to the affected tissues. He accomplishes this by polar electrolysis, placing a negative electrode, impregnated with a 20 per cent. solution of sodium salicylate, on the neck, with the positive electrode on the abdomen or on the back in the lumbar region. The current he prefers is from 15 to 50 milliamperes, and each sitting is half an hour in length. Under the influence of the galvanic stimulation and of the specific drug the cervical rheumatism rapidly subsides. The attacks of migraine become milder and recur at longer and longer intervals until they finally cease altogether. On account of the tendency to recurrence it is advisable to resume the electric treatment with a few sittings from time to time. Hartenberg has treated a number of patients on these principles in the last two years, the results corroborating his conception of the causal mechanism and suggesting that possibly something of the kind may be a factor in other neuroses, especially in certain forms of epilepsy.

26. **Circular Incision of the Leg for Varices.**—Hårdouin's technique is practically the same as when commencing amputa-

tion of the leg, the incision running around the limb. He has found the results extremely satisfactory, rapidly curing the severest cases of varicose ulcers and doing away altogether with the possibility of recurrence. One of the most remarkable benefits of the operation is the way in which the leg shrinks to normal size almost at once afterward.

28 (No. 7.) La splénectomie contre l'anémie splénique et la maladie de Banti. B. Schiassi (Bologna).

29 Mortalité par tuberculose en France et en Allemagne. (Germany).

28. **Rational Operative Treatment of Splenic Anemia.**—Schiassi reviews the history of splenic anemia and Banti's disease and their operative treatment. In certain individuals, he says, the spleen seems to be less resistant than normally and infectious germs are liable to locate in that organ and to cause structural changes which may induce functional disturbances. Removal of the spleen is a logical method of treatment, but is not proving so satisfactory in practice as was expected. Schiassi believes that the trouble in splenic anemia, with or without cirrhosis of the liver, is some metabolic, biochemical phenomena which affect the blood injuriously in the interior of the spleen and nowhere else. Treatment should aim to reduce the quantity of blood circulating sluggishly in the enlarged interspaces and to hasten the circulation through the spleen. To obtain this double result he tries to induce the formation around the spleen of a large capsule of connective tissue. This he accomplishes by introducing broad overlapping strips of gauze to form an envelope of a single layer of gauze entirely around the organ after most of its surface has been scraped with the sharp curette. The incision is sutured in tiers, with the ends of the strips of gauze emerging. On the fifth or sixth day the upper strip of gauze is pulled out and the other strips on the succeeding days, one each day until all are removed by the ninth or tenth day, and the rest of the incision can be sutured. The result of this irritation of the surface is the formation of a large amount of connective tissue, which clings to the spleen, reducing its size and congestion, while a network of new veins forms and diverts part of the circulation from the interior of the spleen. He has performed this operation on two patients with splenic anemia. In the first patient the hemoglobin had been reduced to 24 per cent. and the white corpuscles to 1,800 to the cubic millimeter, while the spleen measured 18x32 cm. Four months after the operation the hemoglobin had increased to 92 per cent. The hemoglobin in the second patient had been reduced to 40 per cent. and there were only 4,000 white corpuscles to the cubic millimeter, while the spleen measured 30x20 cm. In the course of three months after the operation the hemoglobin reached 84 per cent. The spleen in each case had become reduced to one-fifth its former size. The great improvement thus gained has persisted unmodified for a year. He regards fresh bone marrow and rest in bed, with abundant feeding, as important adjuncts for operative treatment. He has had no experience with this operation in Banti's disease, but thinks that omentopexy supplemented by this procedure is theoretically indicated, the former suppressing the ascites and the latter putting an end to the morbid intrasplenic metabolic phenomena. He operated four years ago on a woman with pronounced splenomegalia and cirrhosis of the liver with ascites, a typical case of Banti's disease, his intervention consisting in omentopexy and splenopexy. The patient is still in comparative health, the great improvement realized persisting to date.

30. **Bilateral Empyema.**—Lauche has had 2 cases of bilateral empyema in his charge. One patient was a young man convalescing from pneumonia. Severe hemorrhage from the lungs followed an exploratory puncture of the second lung after the other lung had been punctured and was healing. The pus was removed by resection of a rib in the back. The patient succumbed in the second case, in which the empyema was of actinomycotic origin.

31. **Antihemolytic Test for Blood.**—This new test for forensic differentiation of blood spots was described recently in these columns on page 310. Further experience, Neisser states, has confirmed its delicacy and reliability.

33. **Inhibiting and Anesthetic Action of Magnesium Salts.**—The latest report on Meltzer's work with the magnesium salts was published in THE JOURNAL, March 3, 1906, page 647.

37. **Liver in Treatment of Hemeralopia.**—A few cases have been published here and there of remarkable benefit or cure of hemeralopia by feeding the patients with liver substance. Fabry reports another case in which the same remarkable result was obtained when the patient was given from 200 to 250 gm. of raw sheep's liver on three successive days. The patient was the native guide on an expedition in Africa. During the day his eyesight was above the average, but as the sun set he was unable to see at all. The affection had lasted three months, but subsided after the liver had been taken for three days.

44. **De Beule's Button for Gastroenterostomy.**—De Beule remarks that a year's experience has confirmed the superiority of his button, which has now been used in 22 gastroenterostomies. It is a mechanical impossibility for the vicious circle to develop or for any bile or pancreatic juice to find its way back into the stomach. The passage through the button turns to form a right angle, the opening into the stomach being in the top of the button, while the opening in the duodenum is in the side. By this arrangement it is almost impossible for fluids to find their way around the button and to pass backward through it. Eight different surgeons have used the button to date, including Bier, Gersuny and De Beule himself, and the mortality has been only half that reported by the best surgeons from other methods. The new button has certain special features that commend it for cancer cases, he adds. It much shortens the gastroenterostomy and allows the patient to be fed from the first day.

45. **Technic for Removing Foreign Body or Concrement from Male Urethra.**—Schroeter has been successful with the following simple procedure: If any urine is able to escape past the

foreign body, the outer orifice is closed with the fingers and the patient is instructed to urinate as much as he can, forcing the urine into the urethra until it is much distended with it. The orifice is then abruptly released and the escaping flood sweeps out the foreign body with it. If no urine is able to pass the foreign body, he applies a constricting band above it and then injects water into the urethra to distend it from below, compressing the orifice and allowing the fluid to escape suddenly when the urethra has been sufficiently distended.

51. **Technic of Congestive Hyperemia.**—Mindes gives an illustration of the elastic roller and band which he uses for inducing congestive hyperemia. The aim is to induce red hyperemia; if too weak, the constriction does no good; if too strong, it causes blue or cold hyperemia and is liable to do serious damage. Consequently the roller band, allowing more accurate technic, has been found a great improvement. The roller is wound up with a key to the proper notch, where it is held by a click, holding the broad elastic band firmly in place.

52. **Two Rhino-surgical Interventions.**—One operation described by Grünwald was for the exposure of the interior of the nose and of all the accessory cavities at once, the particulars of the two incisions required being shown in two illustrations. The second operation illustrated is the resection of the vomer as the final step in the radical operation on the frontal sinus.

55. **Laminectomy and Division of Nerves for Neuralgia.**—Oehler commends an operation which he performed, after removal of a cancer in the breast, to cure the intense pain resulting from compression of the brachial plexus by some metastatic nodules. He exposed the dura by resecting the right arches of the fourth, fifth, sixth and seventh cervical vertebrae and of the first dorsal. He then resected the posterior roots of the fifth, sixth, seventh and eighth cervical nerves and of the first thoracic nerve. The wound was sutured at once without drainage, and the relief from pain amply justified the interference. The arm became entirely paralyzed, but this was inevitable from the way in which the nerves of the arm were imbedded in the metastatic nodules.

56. **Application of Water Power to Surgery and Orthopedics.**—Machol describes a method of correcting deformities by constant pressure, in use at Garre's clinic, in which the motive power is a stream of running water. The force is equable, can be exactly controlled, acts automatically and has other advantages which he enumerates. An illustration shows the apparatus adapted for correction of scoliosis. The patient lies on a duck extension table, the extension being applied to head and pelvis. The frame of the table is made of two pipes connected with the water system. An arching frame fits on the pipe and carries the pump contrivance with the attachment for applying the correcting pressure. A little manometer on each pump shows the exact pressure of the water. The water pipes can have as many branches as desired to apply correction at various points. The power applied is very even and constant, and can be kept up for hours under precisely similar conditions, the pressure yielding to and following the part to be corrected. He gives an illustration of the apparatus adapted to apply the water power in mobilizing joints, etc.

57. **Cesarean Section.**—Olshansen or his assistants have performed Cesarean section in 138 cases. In 7 it was on account of eclampsia, in 6 for myoma, in 4 for carcinoma, in 5 on account of vaginofixation, in 3 for nephritis, in 2 for heart disease and in 2 for cicatricial stenosis in cervix or vagina. In two of the women Cesarean section was done twice, in 2 three times and in 3 four times, and these 12 patients with contracted pelves all recovered from their twenty operations. In 4 other cases the Cesarean section was followed by double ligation of each tube and excision of the part between the ligatures to prevent conception later. Olshansen's experience has been decidedly in favor of a very high incision in the abdominal wall, extending above the umbilicus and not approaching nearer than 8 cm. to the symphysis. The incision in the uterus must always avoid the placenta. Its site can usually be determined by the network of veins on the uterine wall. The anterior wall of the uterus usually protrudes more than the posterior wall when it carries the placenta. The course of the round ligaments is not a reliable guide. He never has hemorrhage when he injects ergot twenty minutes before the operation. His dose is 2 gm. of a 6 per cent. aqueous solution of ergotin, with 1 or 2 more gm. later, if necessary. The child is not injured by the ergot. The uterus should be straightened and the incision made in the median line. Compression of the cervix is superfluous and even injurious, as hemorrhage is liable to follow its suspension. He sutures with soft catgut, sterilized in alcohol-carbolic solution, and makes from eight to twelve sutures, taking up as much muscle substance as possible in each stitch, avoiding the peritoneum and decidua, and concluding with a running suture of the peritoneum, including a little of the muscle wall. In the 91 operations done for contracted pelvis he operated personally in 65 cases with 3 deaths, and his assistants in 26 cases with 6 deaths.

58. **Prevention of Puerperal Morbidity.**—Zweifel reiterates his former assertion in regard to the advisability of wiping out the clots of blood which accumulate in the rear of the vagina after childbirth. He is convinced that they form a nest for germs, and now makes a point of removing them on his first visit to the parturient, a few hours after delivery. The clots are wiped out with a dry cloth through a speculum or removed with forceps if the woman is unable to force them out herself. The morbidity in the last series of 243 births was 5.7 per cent. During the last half of 1904, when rubber gloves were used and the vagina was thus wiped out dry, the morbidity in 629 cases was only 7.7 per cent. Over 92 per cent. of the patients recovered without temperature, including several with gonorrhea or lues.

59. **Vaporization of Uterus.**—Baisch shows in colored plates the histologic findings after application of steam to the interior of the uterus. The effect depends on the thickness of the mucosa; the thinner it is the more effectual the cauterization by the steam. The experiences at Döderlein's clinic indicate the advantage of preceding the vaporization with enuretment with an interval of about six days. Any infection, septic or gonorrheal, either of the uterus or adnexa, must be regarded as a contraindication for vaporization. The only cases for which it is adapted are those of pure, uncomplicated, preclimacteric hemorrhages. For such cases vaporization is a much more con-

servative procedure than total extirpation, and the results by the above technic proved invariably satisfactory in Baisch's experience. He has thus treated 15 women.

61. **Lactic Acid in Fluids of Eclampsics.**—Zweifel's assertions in regard to the importance of lactic acid as an etiologic factor in eclampsia were mentioned recently in these columns on page 545. His statements are confirmed by the finding of the same salt of lactic acid in the cerebrospinal fluid of 3 eclamptic women.

62. **Cesarean Section for Varices in Vagina.**—Brunet's patient was a young primipara who had had repeated hemorrhages from the vagina since the onset of labor. The moment the tampons were removed the bleeding recurred. Only 2 patients were saved under these conditions in the 18 cases on record, but mother and child recovered in this case after Cesarean section. The varices rapidly subsided afterward. It is possible that injections of ergot in time might have aided in controlling the hemorrhage.

65-68. **Hebotomy: Extramedian Symphyseotomy.**—Bumm has performed this operation 13 times and healing was by primary intention in all but one case. There were no after-disturbances in the gait, and the children were all born alive. Stoeckel thinks that this operation should be restricted to pelves with a conjugata vera of not less than 8 cm., although it might be possible, he adds, to saw the pubic bone on each side and thus to enlarge the pelvis sufficiently even in the severer cases. Döderlein has performed the operation in 16 cases, leaving all the mothers and children in good condition. He indorses Zweifel's advice to await spontaneous delivery after the bone has been sawed. Tandler discusses the anatomy and technic of the operation, analyzing 19 of the latest cases that have been published by others. Rosenfeld reports research on the cadaver which shows the necessity for varying the technic to suit the particular kind of pelvic deformity.

69. **Improved Catheter to Prevent Cystitis.**—Gersuny ascribes to mechanical injury of the bladder wall a certain proportion of the cases of cystitis that develop after repeated catheterization. In order to prevent this he uses a short curved glass catheter with a projecting shoulder, which prevents its entering beyond a safe distance. In 35 cases in which this catheter was used after operation, cystitis developed in only one instance, although slight urethritis was observed in 4 cases. The patient with cystitis had required catheterization thirteen times and the others four or five.

72. **Congestive Hyperemia in Gynecology.**—Kroemer uses for the suction speculum a wide glass tube with a rubber tube connecting it with the suction pump and a graduated reservoir. His experience suggests that this method of treatment may prove admirable for acute inflammatory processes in the genitalia and for localizing an infectious focus. He thinks it should be of value also in treatment of the consequences of inflammatory processes, either by the active-passive hyperemia to soften strictures and scar tissue, promote absorption of infiltrates, etc., or for the relief of passive hyperemia, in which case it is best to combine it with scarifications. The latter combination might prove effectual, he says, in promoting involution of the puerperal uterus.

77. **Treatment of Osteomalacia.**—In Theilhaber's case the patient was clinically cured of osteomalacia by removal of the sound ovaries by way of the vagina. A year later monthly hemorrhages were noticed resembling menstruation and the symptoms of osteomalacia recurred. The bleeding was traced to a polyp in the uterus; after its removal the hemorrhages ceased and the symptoms of osteomalacia subsided also. He explains osteomalacia as an affection of the metabolism. Removal of the ovaries has a modifying effect on the metabolism. Other measures which modify metabolism are liable to prove useful also in osteomalacia, including venesection. In his case the pains vanished at once after the removal of the ovaries.

80. **Menstruation of Nursing Women.**—Essen-Müller states that menstruation reappeared in 60 per cent. of 427 women nursing their infants whom he examined. Menstruation appeared during the first two months after childbirth in about one-third. Mayer found a proportion of 57.8 per cent. in 685 women. The reappearance of the menses soon after childbirth, he states, may thus be regarded as a normal phenomenon.

83. Superheated Air in Gynecology.—Jung confirms his previous announcements in regard to the great efficacy and value of local application of superheated air as a means of promoting absorption of the products of acute and chronic affections of the adnexa and connective tissue in the pelvis. He has applied it in 137 cases. It avoids the injurious influence on the nervous system inevitable with some of the older methods requiring local manipulations. The pus or effusion is evacuated by an incision, with drainage, and then the superheated air is applied. After the patient is rubbed off she can go out of doors almost at once without danger of chilling. All acute processes contraindicate superheated air, including all febrile patients and those in whom pronounced hyperleucocytosis indicates impending or recent suppurative softening. High fever and other inconveniences are liable to be observed if superheated air is applied in these conditions. The special indications for it are exudation in the connective tissue or inflammatory tumefaction of the adnexa, chronic pelvic peritonitis with adhesions, or chronic indurations and cicatricial tissue in the pelvic connective tissue. It is astonishing sometimes how the old, hard masses soften and vanish under the influence of the hot air. Further indications are the cases with pus requiring incision. After evacuation of the pus and decline of the acute symptoms the hot air will aid in the absorption of the remains of the morbid process. Still another favorable group includes those with exudation in the stump after an operation. Hysteroneurasthenic disturbances are not benefited by the hot air, except, possibly, from the suggestion.

84. Tuberculin Treatment for Febrile and Out-Patients.—The warning is generally given that fever contraindicates tuberculin treatment. Krause has been giving a course of tuberculin treatment to febrile and other patients for whom sanatorium treatment was impossible. The results have justified his expectations, benefit being apparent in every instance. He used Koch's bacillus emulsion in a 1 per cent. dilution in salt solution, the dose of bacillus substance ranging from .005 to .03 mg. In the milder cases all the catarrhal manifestations were banished and they were always mitigated in the severer cases, while the fever vanished permanently in all. This effect on the fever in cases in which it had resisted all other measures was most striking, as also the benefit in the laryngeal tuberculous processes.

85. Brachialgia.—Brassert describes a case and declares that probably many cases of supposed traumatic reflex neuralgia are in reality cases of brachialgia. Treatment should be by suggestion and general, not local, measures. Local applications and advice to rest and to spare the arm merely perpetuate the brachialgia. Prompt recovery is the rule when treatment is by diversion and use of the arm.

89. Hebatomy: Extramedian Symphyseotomy.—Bauerisen concludes his extensive monograph on the subject, based on considerable personal experience, with a discussion as to whether or not delivery should be left to Nature after the pelvis has been enlarged by sawing the pubic bone. He thinks that natural delivery should be awaited after the bone has been sawed through.

90. Operations in Sauerbruch's Air Chamber.—Sauerbruch reviews the 15 important operations on heart, lungs or esophagus that have been done with the aid of his air chamber. It allows the lung to expand in an atmosphere with a pressure below that of the surrounding air. The chamber has been described fully in these columns. He relates that when the thorax was opened wide the respiration and pulse remained natural and normal, even in the case of one patient who was much debilitated from cancer of the esophagus and from addition to alcohol. The results of the experiences since March, 1904, when the chamber was first used, have fully realized many of the hopes aroused by the results of experiments on animals.

91. Inoculation of Monkeys with Tuberculosis.—The experiments were made in Sumatra. A large number of gibbons had been collected by the Dutch authorities on the island for the experiments. Von Dugern remarks that it was astonishing to see the small amount of food (ripe fruit) required by the monkeys to keep them in good condition. No difference could be discovered in the effect of human and of bovine tubercle bacilli when inoculated into the monkeys. The facts observed corroborate the dangers for man of infection with bovine as well as with human tubercle bacilli.

92. Fatigue Toxin and Antitoxin.—This is Weichardt's fourth communication on this subject. He here announces that the albumin molecule has the tendency to split off certain toxic substances as it breaks up. These toxic substances, he states, are by-products in the formation of stable compounds. According to his conception, the fatigue toxin is thus neither a product of reduction nor of oxidation, but a by-product that originates as the albumin molecule begins to break up and one that induces the production of a specific antibody.

96. Snake Bites.—Recent research on this theme is reviewed in this article and the various methods of treating snake bite are enumerated. Lotze suggests that a cupping apparatus, connected with a suction pump, such as Bier uses to induce congestive hyperemia, might be found useful for sucking the venom out of the wound. Calmette's antivenene should be used when procurable, but if not, a 2 per cent. solution of chlorinated lime should be injected. This tends to neutralize the toxins by the gases generated. (See article in miscellany column, March 10, 1906, page 749.)

97. Prophylactic and Therapeutic Use of Antistreptococcus Serum.—Fromme has been making a practice lately of injecting 10 c.c. of antistreptococcus serum three or four hours before undertaking an important abdominal or vaginal operation. In 11 out of 13 cases of uterine cancer the after-course of the cases was exceptionally smooth, and likewise in 8 cases of other gynecologic affections similarly treated. The general impression was decidedly favorable in regard to prophylactic use of the serum. In several other cases it was administered for therapeutic purposes and the results were less strikingly beneficial. On the whole, the verdict is in favor of its prophylactic use and also for the treatment of incipient streptococcus infections. In case of postoperative peritonitis requiring secondary incision and drainage, the serum may be useful as an adjuvant, but little can be hoped from it in pyemia and septicemia and in infectious processes of long standing. Any powerful reaction will only do harm in this latter case.

101. **Differentiation of Thrombosis of Portal Vein from Peritonitis.**—Solieri's case of thrombosis of the portal vein complicating round ulcer of the stomach had been diagnosed as peritonitis from perforation of the gastric ulcer. He analyzes the similar cases on record, stating that only one was correctly diagnosed during life. Only a few of the patients could be cured by operative intervention. In differentiation the possibility of existence of changes in the liver liable to impede the normal circulation should be borne in mind. The symptoms are like those of perforation peritonitis. Bloody diarrhea is characteristic, but it may be substituted by ileus, as in the case described. The patient's face was pale and ashy, but not contracted as in case of peritonitis. He experienced intense pain, but the abdomen was not so extremely sensitive to pressure as in peritonitis from the inflammatory irritation of the nerve terminals in the parietal peritoneum. The abdominal wall was not rigid and there was no hicough. There was much more effusion than is common in peritonitis, and it recurred rapidly after tapping. The alarming symptoms come on more slowly in case of thrombosis than in peritonitis from perforation.

102. **Radiotherapy of Primary Syphilitic Lesions.**—The writers' experience with x-ray treatment of the primary inguinal bubo shows that such lesions react to the exposures with inflammatory phenomena more intense than are observed in any other form of glandular trouble. A large number of experiences and years of observation are required to decide the question as to the further development of syphilis thus treated.

103. **Blood Pressure in Heart Affections.**—Gennari asserts that the blood pressure is always high in case of heart disease or arteriosclerosis whenever there is a complicating kidney affection, and that this may be important in differentiating puzzling cases in which the urine does not indicate renal trouble. He always noticed that patients with cardiac affections improved by treatment in the hospital, had a much lower blood pressure than when first admitted to the hospital. The blood pressure increases or diminishes parallel to disturbances in compensation, and may thus serve for the prognosis.

107. **Treatment of Non-Healing Cavities in Long Bones.**—Ekehorn has been very successful with his technique of lining the cavity in the bone with Thiersch skin flaps. He applies this method in various kinds of acute and chronic affections of the bones leaving a cavity. The procedure is so simple that it can scarcely be called an operation, and if it fails no harm has been done. Healing has not been delayed a moment. If it succeeds—and he has found it especially successful in case of cavities of long standing—then the healing has been materially promoted. Another advantage is that if some small focus has been overlooked it is placed in a favorable condition for healing. One of his patients had suffered from osteomyelitis of the lower end of the femur for twenty-five years and had been operated on six times. Again and again the process would recur, and there was always a dull, heavy sensation in the limb and occasionally pain and fatigue. After five years' intermission the process broke out again in an acute form in 1902 and again a year later. It was carefully treated according to the usual measures, but again broke out in 1903. Ekehorn then performed Thiersch transplantation. The cavity was first scraped to sound tissue and tamponed. After two or three days the Thiersch flaps were applied directly from the knife. They were cut in strips long enough to reach from the center of the bottom of the cavity to the edge of the wound in the skin, passing over the bone walls and soft parts. When the cavity was thus lined it was tamponed, using a "tampon tube" for the purpose, and a dry dressing was applied outside. The tampon was left for four or five days until it could be removed without disturbing the flaps. They healed in place in a week or less. The patient was freed at once from all his disturbances and can now use his leg normally without fatigue. Another patient with an osteomyelitic

fistula of long standing was cured in the same way by the Thiersch skin flaps. Another patient was a man of 68 who had had recurring osteomyelitis in the upper end of the tibia since childhood. After failure of other treatment this treatment completely cured the lesion and the tendency to recurrence. The results seem to be particularly fine in these old cavities. The strips of granulations between the flaps soon heal over completely and the part has a permanently healthy aspect.

108. **Operative Treatment of Spastic Torticollis.**—Berg presents evidence to show that the drawbacks of operative treatment are comparatively trifling in case of spastic wry-neck. Success can be expected only when the operation is extended to conform to the indications of each individual case. In by far the larger majority the muscles of the neck are involved as well as the sternocleidomastoid, and consequently severing the spinal accessory nerve alone does not meet the indications. In the 5 cases reported the cervical nerves and the accessory were divided at different sittings in 3, and the result of each of these partial operations was precisely what was to be expected from the anatomic conditions. This excludes the idea of suggestion as a factor in the final success. All these patients were cured, although a very slight tendency to deviation of the head is still observable in repose. In another case the accessory nerve was merely stretched and psychic treatment according to Brissaud instituted, with the result of a rapid cure to date. Before resorting to surgical measures Berg advises the most extensive application of the Brissaud system of psychic treatment. If operative treatment becomes necessary the prospects are better, the smaller the region involved and the less the psychopathic tendency. Unless the sternocleidomastoid is unmistakably and prominently involved in the spasm, it is useless to resect the accessory nerve. The operation on the posterior branches of the superior cervical nerves should be restricted to division of the second branch at the intervertebral foramen and cautious division of the two contracted muscles at their insertion on the transverse processes of the atlas.

109. **Ectopic Ovary.**—In the case described, a woman of 42 with otherwise normally developed genitalia, was operated on for a congenital inguinal hernia. The hernia was first noticed three years before, and it became tender at the time of the menses; otherwise there was nothing abnormal. The hernia suddenly began to increase in size and was operated on. It was found to be a cystic tumor of ovarian tissue, probably an ectopic ovary.

THE FORMATION OF URIC ACID.*

LAFAYETTE B. MENDEL.

Professor of Physiological Chemistry In the Sheffield Scientific School, Yale University.

NEW HAVEN, CONN.

The rôle of uric acid in physiology and pathology has long formed a theme for unrestricted discussion and controversy in scientific literature. The wealth of published contributions on this subject abounds in the most characteristic specimens of what a recent medical writer has aptly termed "truth and poetry about uric acid."

Nevertheless the student of the physiology of uric acid can not fail to recognize a number of distinct epochs representing the introduction of new discoveries and consequent altered points of view in the interpretation of familiar phenomena. When the secret of each novel attitude is revealed it no longer becomes difficult to follow the march of progress in science; and, what is all-important, we are thus enabled to revise or formulate anew the problems with the solution of which advancement is coincident.

This society, so happily inaugurated "for the diffusion of the knowledge of the medical sciences," will accomplish great good if its proceedings emphasize that before pathologic variations can be appreciated adequately, some fundamental knowledge of the normal functions of organs is essential. To the neglect of this, as a general rule, is due not a little of the confusion regarding the part played by uric acid in the animal body. Clinical observations, not infrequently confined to isolated cases or limited numbers, and more often carried out with inaccurate methods of research—the so-called clinical methods—have led to theories which were only reluctantly abandoned. Every investigator will admit that an hypothesis is a great aid to research in any domain; but a theory is admissible only so long as it fits the facts. Yet how difficult it is to relegate to the rubbish heap a theory which is supported by the authority of a distinguished worker. The present generation of scientists is learning to present truths eagerly, but to generalize from them with caution.

EARLIER VIEWS.

The obstacles to scientific progress which I have just referred to are well illustrated by some earlier views on the origin of uric acid in the body. Since urea was recognized as an end product of the oxidative decomposition of proteids nothing was easier than to assume that the larger molecule, uric acid, represents a product of incomplete oxidation. Whether uric acid was regarded as an intermediate product in the combustion of the large proteid complex or whether it was, rather, the out-

come of an abnormal or irregular disintegration change—in either event it seemed proper to attribute an increased occurrence of the compound to a disturbance in the usual oxidation of ordinary proteids. In clinical language the vague uric-acid diathesis became the expression of an equally vague lowering of the oxidative capacity of the organism. It was observed, for example, that leukemia is often accompanied by an increased output of uric acid in the urine; and at once the theorists attempted to associate this with an insufficient oxygen-carrying capacity of the circulating blood, in connection with a relative diminution in the number of erythrocytes. The increasing number of cases reported failed to show any constancy in the increase of uric acid excreted. When finally the crucial physiologic experiment of interference with respiration was made, no increase of uric acid was noted; and, above all, when the actual conditions in disease were experimentally investigated, it was found that leukemia is not attended with any deficiency in oxidative powers. With these negative results the structure of the old theory of the incomplete oxidation of proteid fell. How much would have been gained in this instance alone by a more inductive method of study.

My subject is restricted to one aspect of the physiologic problems concerning uric acid, namely, its formation in the body. How many erroneous ideas have arisen from a mistaken identification of the excretion of uric acid with its formation no one can say. So long as uric acid was looked on as one of the end products of nitrogenous catabolism the confusion was a natural one. We have, however, lately come to recognize this chemical compound as an intermediary product which may, in turn, experience ready decomposition within the body. With this once clearly recognized it is evident that the amount of uric acid eliminated within any given period is not necessarily any adequate index to that which has been formed within or introduced into the organism; and this statement applies independently of any undue retention to which attention has been directed so zealously by certain writers. The physiologist is to-day in a position to recognize the precursors of uric acid in the ingested foods or the disintegrating tissues and likewise to estimate with accuracy the quantities of these compounds which escape from the organism unchanged. And if the chemical and physiologic history of the intermediary transformations is not yet unfolded in its entirety, we can at least report commendable progress.

A review of early theories is unnecessary.¹ Manifold

1. For a comprehensive review of the older literature on uric acid in physiology and pathology, the reader is referred to the papers by Wiener: *Ergebnisse d. Physiol.*, 1902, vol. 4, part 1, 1903, vol. II, part 1; Burian and Schur: *Müller's Arch.*, 1900, vol. lxxx; 1901, vol. lxxxv; Walker Hall: "The Purin Bodies of Food-stuffs," 1903. No attempt is made in the present paper to give a complete list of the newer investigations, only the more important references being noted.

* Read before the Harvey Society of New York at the Academy of Medicine.

experimental investigations have long since demonstrated the untenability of the view ascribing the origin of uric acid to a decomposition of simple proteids, in which it might arise as an antecedent of urica. Similarly the notion of attributing the production of uric acid to a diminished oxidative capacity in the body as a whole may be dismissed, although we shall see that certain greatly modified aspects of this view have again arisen in other connections. The more adequate, or what may appropriately be termed the modern conception of the formation of uric acid is associated especially with the researches of two investigators, Kossel and E. Fischer.

THE WORK OF KOSSEL AND E. FISCHER.

E. Fischer definitely established the chemical structure of uric acid and a large group of related compounds which have become familiar, through their physiologic and pharmacologic bearings, as the xanthin compounds, the alloxuric compounds or (more appropriately) the purin compounds. No physician can hope to have an adequate appreciation of the problems under discussion without some familiarity with the chemical structure of this group of related substances. The formulæ here presented therefore demands no apology; a superficial inspection alone reveals relationships which a page of description can not make equally evident.

Kossel's epoch-making contribution consisted primarily in his demonstration that the purin compounds, such as xanthin and hypoxanthin, are disintegration products of the widely distributed nucleoproteids, nucleins or nucleic acids. In one of his earliest papers, in 1881, recognizing the near chemical relation of the purin compounds to uric acid (see formulæ), he wrote: "The thought is at once suggested that these compounds play a significant rôle as normal precursors of uric acid or urica. The difficulty involved in the recognition of this lies in the circumstances that these substances have heretofore been found in organs in small quantities only." Kossel² proceeded to show that the proportions of the different purin derivatives present in or obtainable from the body is far greater than had been anticipated.

The earliest experimental attempts which might have served to verify Kossel's hypothesis gave negative or uncertain results in almost every case. These failures are in part explicable in the light of subsequent study. A part of the difficulty is ascribable to inadequate analytical processes, a fact which is deserving of note at a time when the patient endeavors of the students of accurate analytical methods receive scanty appreciation from those who have no immediate use for them. Uric acid was at first missed as an end product of hypoxanthin-feeding, guanine-feeding and nuclein-feeding, partly owing to inadequate methods, in part probably because of poor absorption of the ingested materials, and more likely, further, because of the destruction of the formed

uric acid in the intermediary metabolism of such species (dog, rabbit) as were inadvisedly selected for the trials.

HORBACZEWSKI'S EXPERIMENTS.

In 1889 Horbaczewski gave a new turn to the experiments and theories on uric-acid formation. To him was due the first experimental proof of the transformation of purin compounds into uric acid. By digesting organs like the spleen, rich in nucleoproteids, with blood, he obtained either the purin bases xanthin and hypoxanthin, or uric acid, according as his experiments were conducted in the absence or presence of oxygen. These experiments have become classic. But Horbaczewski made an equally important addition when he fed the nuclein prepared from spleen pulp and succeeded in eliciting an increased output of uric acid in both man and animals, thus transferring to the living body the experience gained in the digestion beaker.

Horbaczewski was unfortunate in the explanation which he gave for this new production of uric acid. He attributed it to the disintegration of nucleoprotein material, it is true; but he persistently refused to credit the increase to the purin-yielding substances ingested. Accordingly, he invented the theory of a leucocytosis induced by the ingested nucleoproteids, leading in turn to a breaking down of body cells,—leucocytes rich in the purin-bearing nucleic-acid groups. That the introduction of nucleic acids, either as such or as proteid salts (nucleins, nucleoproteids) may lead to an increased elimination of uric acid has since been demonstrated for many compounds of both animal and vegetable origin and in a considerable number of animal species; but the evidence is to-day abundantly in favor of a direct transformation of the ingested material without the intermediation of leucocytes. An increase in the digestive leucocytosis under this condition of feeding is the unusual rather than the usual occurrence; and the experience which I have gathered with my co-workers indicates that a characteristic metabolism of the purins follows the most diverse modes of introduction of the mother substances into the organism. Parenteral paths are equally effective.

THE PURINS AND URIC ACID.

The failure of the earlier attempts to demonstrate in animals a conversion of ingested free purin bases, such as are obtained by the destruction of nucleic acids and nucleins, into uric acid, raised the question: Is some peculiar chemical complex or union like that of the nucleic acid molecule requisite for the conversion of the purins to uric acid in the body, or can the free purin bases be thus converted? For example, can guanine or adenine as such be transformed to uric acid, or is the characteristic oxidation dependent on the manner in which these purin bases are bound up in nucleic acid and such uric acid forming products as thymus gland? It is conceivable that hypoxanthin, for instance, might exert a leucocytotic action such as Horbaczewski assumed for the nucleins; in that event the increased formation and destruction of leucocytes would presumably be accompanied by an increased elimination of liberated phosphoric acid. Krüger and Schmid³ have made these questions superfluous by demonstrating that even in man the ingestion of hypoxanthin, xanthin, guanine or adenine is followed by an increase in the output of uric acid. They have made clear that this phenomenon is in no

3. Krüger and Schmid: Zeltft. f. Physiol. Chemie, 1902, vol. xxiv, p. 549. Earlier observations on hypoxanthin were reported by Minkowski and by Burton and Schur.

2. Kossel: Zeltft. f. Physiol. Chemie, 1881, vol. v, p. 267.

way the outcome of a leucotactic action of the free purin bases fed and that the phosphoric-acid metabolism of the body undergoes no noticeable alteration which would indicate any coincident destruction or synthesis of nucleic acid in the tissues.

With the genetic relationship between the purins of the food, whether in the form of the free hypoxanthin of meat extract or the nucleoproteids of glandular tissues like sweetbreads and liver once established, it is instructive to consider the quantitative relations between these two factors in metabolism. To what extent do the purins introduced contribute to the increased production and elimination of uric acid? When a balance is struck between the intake of purins, either free or combined, and the increase in output of uric acid in the urine as a measure of its production from the ingesta, a deficit is uniformly detected. It might be assumed that the purins fed are in part eliminated unchanged; indeed, it is well recognized that the urine contains other purin derivatives than uric acid. The quantity of these is, however, not appreciably or significantly altered by purin feeding except under unusual circumstances. A few actual figures will serve to illustrate the deficit to which reference has been made. Thus, in one case in man after feeding 1.2 gm. of nitrogen in the form of hypoxanthin, 0.77 gm. was recovered as excess of uric acid, or about 62 per cent.; in the case of adenin 33 per cent. was recovered as uric acid, and less than 4 per cent. left the organism unchanged.⁴

DESTRUCTION OF URIC ACID.

The failure to recover the entire quantity of ingested purin in the form of uric acid or unchanged urinary purin suggests two explanations: 1, A retention of a portion of the purins or the uric acid formed therefrom so that they fail to reappear in the urine; or 2, a destruction of purins in the metabolic exchanges. The retention theory has been abandoned by almost all investigators except the followers of Haig, whose theories I regard as irreconcilable with modern experimental evidence. The question of the destruction of purins in the body, though foreign to the real subject of this lecture, nevertheless deserves brief consideration.

It has long been known that very considerable quantities of uric acid itself can be destroyed in the body. The evidence for this is made more convincing by the studies on various isolated organs in which this destruction has been investigated directly. For example, when blood containing a solution of uric acid is perfused through a surviving liver a progressive loss of uric acid takes place. The quantity of uric acid eliminated or found at any moment is therefore by no means an index to the quantity formed. The recognition of this fact, of the power of the animal organism to catabolize uric acid like other nitrogenous compounds, is one of the fruits of modern research which has profoundly changed our attitude toward the problems of purin metabolism.

The extent to which the destruction of uric acid and other purins actually takes place varies in different animal species. Burian and Schur⁵ have made an elaborate study of this subject and reached the conclusion that the proportion of the ingested purins which escapes destruction and is therefore eliminated as uric acid, is rather constant. In carnivora, like the dog and cat, it is about 1/20; in herbivora, like the rabbit, 1/6, and in man 1/2 of the purin material introduced. This explains why so little uric acid is ordinarily found in the

urine of the familiar laboratory animal, the dog, in contrast with man. It is furthermore probable that young animals are not equally capable of effecting the destruction of uric acid, and it is not unlikely to me that similar defects may be associated with pathologic conditions.

If we summarize these recent findings respecting the destructive capacity of the body for uric acid, a new point of view arises in the discussions of the so-called uric-acid diathesis. Uric acid formed in the body is ordinarily largely destroyed in the body again; it may therefore occur in unusual amount owing to diminished destruction equally as well as it might accumulate through imperfect elimination or increased production. The important point is that a study of the urine alone will not decide. The tolerance of the organism for purins must be ascertained by a comparison of the intake.

What are the end products of this destruction of uric acid in the organism? Urea is at once suggested by the mere inspection of the structural formula. The possible formation of oxalic acid

in the same reaction is also thus brought into view. In the carnivorous dog and cat the observations of Salkowski, Minkowski, Cohn and the work in our laboratory, have indicated that allantoin represents an important transformation product of uric acid and is glycocoll. The chemical relationships involved are made clear by the comparison of the structural formula:

The current views regarding the relative formation of these compounds under different circumstances are still divergent and a discussion of them at this time would be unprofitable.

The review which has been presented up to this point has traversed the paths familiar to every student of this subject. At most the changing ideas regarding the origin of uric acid have been pointed out. The distinctly modern aspect of the problem concerns the mechanism by which the metabolism of the purins is effected—the chemical history of the reactions which yield uric acid from nucleoproteids, and in turn cause its disappearance.

ENZYMES AND PURIN METABOLISM.

That a preponderating rôle is played by soluble enzymes is no longer a matter of conjecture; nor is this anything other than what the increasing knowledge of the importance of these biologic agents would lead us to anticipate. Enzymes are no longer thought of exclusively as agents of the digestive apparatus; they enter everywhere into the manifold activities of cells in almost every feature of metabolism. Hydrolysis and oxidation are facilitated by their participation in definite, conceivable ways. Horbaczewski's⁶ observations on the formation of uric acid *in vitro* from the purins of spleen pulp formed the starting point for the new departure. Spitzer⁷ then demonstrated that extracts of spleen and liver may yield uric acid when air is present, even in the absence of putrefactive processes, thus indicating the enzymatic character of this reaction. He also showed

4. The data are taken from Krüger and Schmid: *Loc. cit.*, p. 559.

5. Burian and Schur: *Pflüger's Arch.*, 1901, vol. lxxvii, p. 335. Cf. also Krüger and Schmid: *Loc. cit.*

7. Spitzer: *Pflüger's Arch.*, 1899, vol. lxxv, p. 192.

that uric acid can be obtained in an oxidative way from adenin and guanine by the action of some constituent of spleen or liver extracts in the presence of atmospheric oxygen, although the formation of uric acid is far more extensive when xanthin and hypoxanthin are the precursors. These results were confirmed by Wiener,⁸ and the facts which they represent are now undisputed.

The additional contributions of Schittenhelm⁹ and Jones¹⁰ have established the co-operation of several enzymes in the steps leading to uric acid as an end product. The first of these involves a nuclease, that is, an enzyme capable of splitting up nucleic acid so as to liberate the purin bases present in its complexes. The constitution of the nucleic acids is by no means determined, although the researches of Osborne¹¹ and of Bang¹² enable one to obtain some conception of the possible relationship of the purin derivatives to the remaining radicals, as indicated in the provisional formulae:

Burian¹³ has lately given reasonable evidence that the purin groups are attached to the remaining nucleic at the 7-position of the purin skeleton, so that guanine, for example, would be attached to the remaining groups as indicated below:

In chemical terms the action of the enzyme nuclease would thus be comparable with the reaction involved in the hydrolysis of an acid amide:

Nucleases are doubtless widely distributed in nature. They must obviously share in many autolytic processes in organs and tissues. At present, however, our information on regarding this class of enzymes is rather limited.

More light has been thrown on a second step in the intermediary metabolism of purins. Several investigators, notably Jones¹⁰ and Schittenhelm,⁹ have succeeded in isolating enzymes of the amidase type which accomplish the conversion of the amino purins, guanine and adenin into xanthin and hypoxanthin, with liberation of ammonia.

Reactions of this kind, attributable to enzyme influence, have long been recognized and assumed to have importance in the deamidizing of nitrogenous compounds in metabolism.¹⁴ For the cases under consideration the reaction may be assumed to proceed as follows:

In correspondence with this, adenin and guanine are converted into hypoxanthin and xanthin, respectively, when they are digested with extracts of certain tissues. An interesting controversy has arisen in the study and developed into more than polemical interest. Having obtained extracts of organs which readily deamidize adenin without converting guanine, Jones very properly postulated the existence of two distinct amidases—guanase and adenase. Working with the same organ (the spleen), Schittenhelm has failed to note any such distinctive difference. The discrepancy has lately been cleared up by the discovery of Jones,¹⁰ that whereas the spleen of the ox (with which Schittenhelm experimented) contains guanase, it is missing in that of the pig (which formed the source of Jones' experimental material); and the latest experiences of Schittenhelm¹⁵ and of Pfeiffer¹⁶ add to the growing conviction that the distribution of the enzymes concerned in the metabolism of the purins is very unlike in different species. Future studies in this field will doubtless contribute many features of interest in comparative physiologic chemistry.

That these enzymes are not universally distributed in all organs and tissues is certainly not without physiologic significance. Up to the present adenase and guanase have been found in the spleen, liver, lung, muscle, thymus and suprarenals; not in the intestines, blood or kidneys.¹⁷ When tissue extracts prepared from spleen, liver, muscle or lung are allowed to act on guanine or adenin in the presence of oxygen, uric acid is found in place of xanthin or hypoxanthin. In this reaction a third enzyme, an oxidase, is involved, converting hypoxanthin to xanthin and subsequently to uric acid.

Under favorable conditions the conversion may be practically complete. The first step in these reactions may be graphically represented as follows:¹⁸

The final step is the oxidative transformation of xanthin into uric acid. I am unable in the allotted time to give appropriate recognition to the various investigators who have at length enabled us to trace in some comprehensible way the intermediary changes by which the purins and their nucleic precursors may give rise to uric acid; nor am I permitted to do more than refer to the work of Wiener, Ascoli, Schittenhelm and others,¹⁹ in which the destruction of uric acid by the agency of uricolytic enzymes has been found conspicuous in the kidney and liver, and in lesser degree in extracts of muscle and bone marrow. The sequence of events in the transformation of purins is bound up in a series of typical enzyme reactions.

EYE-STRAIN AS A CAUSE OF DISEASES OF THE DIGESTIVE ORGANS.

GEORGE M. GOULD, M.D.

PHILADELPHIA.

Before the Section on Practice of Medicine of the American Medical Association,¹ in 1905, the then president of the association, the professor of medicine in the medical department of an old university, read these words:

NONGASTRIC ORGANIC DISEASES PRESENTING GASTRIC SYMPTOMS.

The Eyes.—The subject is familiar to all. Who has not seen correction of errors of refraction relieve so-called "bilious attacks," periodical vomiting, anorexia, indigestion and other gastric symptoms? The cure of grave organic ocular defects relieves similar gastric conditions.

A good-sized book, with no superfluous word, might be written concerning this astonishing admission, for: 1. Every statement made is true. 2. Every statement made is untrue. 3. Its significance is wholly unrecognized and far-reaching. 4. The history and due credit-giving are unjustly ignored.

1. Supposing that the thing intended to be said is really said, we have here an authoritative assent and reaffirmation of the truth that eye-strain frequently produces "bilious attacks," periodical vomiting, anorexia, indigestion, and other gastric and intestinal diseases. It is now sixteen or seventeen years since I began to affirm and to reaffirm this truth, and this is the second convert made among the diagnosticians, leading practitioners or gastrologists. Hereafter I can merely refer critics, sneerers, ignorers and deniers to Dr. Musser, ask them to settle their scores with him, and sing my "*Nunc dimittis*" with a smile of cheery satisfaction. No longer is it a question of the opinion of a "specialist," an "enthusiast," an "exaggerator," a "hobby-rider," a "grinder of his own axes," etc., but the president of the largest American medical society, the professor of medicine in a great medical college, and the leading diagnostician and practitioner in a large city, has spontaneously and publicly stamped the theory with the approving seal of his authority. There is abundant clinical evidence of the correctness of the intended statements of Dr. Musser in the paragraph quoted, and any practitioner can verify it in his practice by numerous patients whenever he will refer them to competent oculists and follow the histories up for a few days, a few weeks or a few months. In this instance it is not for the affirmer to prove his statement. Any man who makes such an assertion as this, and especially one occupying the position of authority and power held by Musser, is perfectly aware of the reach and significance of his published opinion. He has, beyond question, demonstrated it long and often, or he would not dare to come out so plainly and without equivocation. It, therefore, behoves the deniers, ignorers and cynics—the so-called "conservatives"—to prove their negation, because, by every moral and medical law, all patients continued in their sufferings by this "conservatism" may justly, and should legally, hold the deniers, ignorers and cynics criminally responsible. We hold the antivaccinationists accountable for every case of small-pox, and it is proverbially "a poor rule that will not work both ways."

How many deaths are chargeable to the prejudices of Hodge and Meigs and their blind adherents who opposed

the clear logic of Oliver Wendell Holmes? And when the error-loving and truth-hating opponents and rivals of Semmelweis ruined him professionally and allowed thousands of their patients to die they were likewise responsible. Since now a great man has authoritatively announced the frequent dependence of diseases of the digestive organs on eye-strain, those who continue their policy of not giving their patients the possibility of cure by the method suggested must settle with avenging science and the medicine of the future. They can not longer continue the pitiful and silly cry of, "Danger, danger in such extremism," with which they and their commercial medical journals have met the demands of progress in clinical medicine.

2. It is a pity that the method of making the announcement of the paragraph was not itself beyond criticism. There is a perfectly well understood and admitted meaning of the term "organic disease." In the paragraph-title, "Nongastric Organic Diseases," etc., this definition is contravened and mystified. Amblyopia is not an organic disease. The eye with the low and common errors of refraction is in no way morbid or diseased, least of all is it organically diseased. Only by secondary endeavors to overcome the malfunction of the ametropic eye does organic disease somewhat rarely arise, either in the eye itself or elsewhere. In the vast majority of cases the attempt to overcome the error—called eye-strain—is purely functional. In the same way, in the last sentence of the paragraph, the repetitive misuse of the term is followed by the words "similar gastric conditions." But the gastric, intestinal and pelvic consequences of eye-strain are at first, and for long, purely functional. As long-continued functional disorder is bound to end in organic disease or anatomic pathology, so here, also, these functional disorders of digestion may finally end in inflammatory and surgical disease.² But a wiser discrimination should have guided in the making of the pronouncement.

The motive may have been excellent which prompted the writer to say, "The subject is familiar to all. Who has not seen," etc.? But method is often almost as important as motive, and in this instance it is doubly or trebly so. If it is correct to say that the subject is "familiar to all," etc., then those who show wilful ignorance of it, those who deny and scoff at it, those who do not bring the possibility of the therapeutic test to their patients—what shall be said of them? Is there any word too denunciatory, any expletive too strong, as applied to one who has seen, often and "familiarly" seen, the relief of eye-strain end bilious attacks, vomiting, anorexia, indigestion and other similar symptoms, and yet who wholly ignores the fact in his published books and articles, who does not act on the suggestion in the treatment of his patients, who scoffs at all reflexes, and who publicly laughs at all such nonsensical theories and theorists. Without the "if," I do not myself call them miscreants and scoundrels—I only ask, if it is so, is it not scoundrelism? The authority implies plainly that all physicians have seen such cures, are familiar with them, know them to be genuine and true—and yet, well, let us glance at the literature! We must remember that there can not be less than one-third of the persons of the civilized world who are suffering from some of these enumerated symptoms and their sequels. There are

2. This is so true that a great surgeon publicly states that his most brilliant cures of threatened operation, appendicitis, peritonitis, and other "surgical" diseases of the pelvis, have been made without operation, and by sending his patients to the oculist.

several hundred millions of such civilized persons, and hence, admittedly, and at the lowest calculation, there must be a score or two of millions suffering from digestive disorders due to eye-strain. Everybody, plainly implies Professor Musser, is familiar with and admits the fact that the correction of eye-strain gives relief in many cases of gastric and intestinal disorder. Well, if so, why do they not say so and report cases publicly? What kind of familiarity and science is that which is carefully excluded from all publication and open admission? It is, of course, sham familiarity, unscience, nonsense.

First, as to the text-books, treatises and monographs on diseases of the stomach or of digestion.

LOAS, 1897, "Diagnostik und Therapie der Magenkrankheiten," does not mention the eyes as possible cause of stomach diseases.

BOAS, 1901, "Diseases of the Intestines" (translation of Basch), is likewise oblivious of the "familiar" fact.

COUNHEIM, 1905, "Krankheiten des Verdauungskanales," if "familiar" ignores the theory utterly.

DEBOVE and ACHARD, 1895, and DEBOVE and REMOND, 1893, "Maladies de l'estomac," also seem unfamiliar with this theory.

EINHORN, 1903, "Diseases of the Stomach," "has not seen," etc., or, if he has seen, has not spoken of the matter.

EINHORN, 1904, "Diseases of the Intestines," utterly ignores the well-known theory and facts that support it.

FLEISER, 1896, "Krankheiten der Verdauungsorgane," would probably agree with the German ophthalmic surgeons in pronouncing such nonsense *Amerikanische Humbug*.

FRENKEL, 1900, "Maladies de l'estomac," should come to Philadelphia and study the subject more thoroughly before he writes again. He wholly ignores the theory.

HEMMETER, 1902, "Diseases of the Stomach," should revise almost every page of his treatise if Professor Musser is correct. He has not heard of the theory.

HEMMETER, 1902, "Diseases of the Intestines," inferentially denies both the facts and the familiarity. He is still silent.

KAHANE, 1900, "Therapie der Darmkrankheiten," is a sorry teacher if he has seen and is familiar with such facts.

MATHIEU, 1900, "Maladies de l'estomac," writes strangely if he knows the rôle that eye-strain plays in those maladies, for he does not speak of it.

MARTIN, 1895, "Diseases of the Stomach," is equally to be criticised.

PICK, 1895, "Magen und Darm-Krankheiten," does not allude to the affair.

ROBARI, 1904, "Magen und Darm-Krankheiten," wrote too long ago, probably, to have heard of facts which in 1905 are "familiar to all."

SOUHAULT, 1905, "Maladies de l'estomac," does not agree that "all" should be construed as including French physicians.

VAN VALZAH, 1898, "Diseases of the Stomach," omits all reference to this source of gastric diseases.

WIGLE, 1905, "Magen und Darm-Erkrankungen," is also not to be included among the "all."

Of all the recent text-books on gastric and intestinal diseases that I could find in the library of our College of Physicians, the 18 mentioned do not contain any reference whatever to what Dr. Musser says is admitted by all. I have found two, however, who do refer to it. The first is:

Reed, 1904, "Lectures on Diseases of the Stomach and Intestines," under the heading, "Acid Gastric Catarrh," p. 825, has these inviting, powerful and emphatic words: "The oculists include eye-strain among the possible causes." And we yearn, beyond consolation, to know what "oculists" so include," and where the references may be found.

The second is:

Herschel, 1895, "Indigestion," under Reflex Causes, p. 11; this ignored teacher does not ignore, and includes himself among the "all." He writes:

"A considerable amount of attention has been paid of late to the possibility of gastric affections being set up reflexly by eye-strain. George M. Gould, in a paper published in 1890 in the *International Journal of the Medical Sciences*," stated that he had found that in the young of either sex eye-strain, to a considerable extent, often interfered with the digestive process. My own experience bears this out, as I have had in my own practice several cases in which digestive troubles appeared to depend on astigmatism. One patient in particular, a chemist in the city (London), a highly neurotic individual, used to suffer from great flatulence during the morning hours. I discovered that he was astigmatic, that he lived out of town and read a paper coming up in the train. He informed me that the flatulence invariably came on as soon as he commenced to read the paper in question. The gastric troubles promptly disappeared as soon as he discontinued reading on his way up to town."

Thus eighteen out of twenty recent systematic treatises on diseases of the digestive organs completely ignore what a great authority says is a well-known and highly important cause and cure of such diseases; one smiles at it in a line, and one devotes to it a half-page—with sympathy and respect, President Musser should gladly note.

How is it with the systematic practices of medicine? A highly important cause, known of all, of a vast number of cases of disease, and the means of speedy cure, should, of course, be extensively and minutely set forth and emphatically urged on the attention of the students and practitioners who receive the teachings of the great scientists and instructors. I have examined carefully the following "Systems," and "Practices," and "Manuals," and Text-books: Leo, Allbutt, Mathien, Ewald, Nothnagel, Debove and Achard, Anders, Bain, Bouchard and Brisseau, Brouardel, Hare, Bartholow, Hughes, Klemperer, von Mering, Monro, Osler, Salinger and Kapterer, Tyson, Gibson, Butler, Hare, Kuhneman, Lyon, Cohen and Eshner and others.

Why do they entirely fail, even in that old foolish allusion, that is meant to be illusion, in the reference that refers nowhere, the indexing that demonstrates the author's omniscience, but also his total unconcern?

But even here the rule has its exceptions, and some unmentionables may be mentioned:

Allchin, vol. v, p. 235, wrote in 1903: Not a few cases of nervous dyspepsia may be traced to causes acting reflexly, especially pelvic disease, and even, it is asserted, to eye-strain and astigmatism.³

French, 1905, has one or two similar strabismic allusions.

Da Costa, 1900, refers to it still more gingerly.

Hare, 1905, "Practical Therapeutics," generously allows two lines to the subject: "Eye-strain may cause stomachic disturbances, flatulent dyspepsia and a variety of general or so-called reflex neuroses."

Musser, 1904, "Medical Diagnosis," is not so generous concerning a factor of great importance in 1905, and one "familiar to all." He allots one word to it:

"Gastric neuroses may arise directly from disease of the stomach or reflexly from disease of other organs, the brain, the spinal cord, uterus, kidneys, liver, eyes or nose."

It is good to know that the eyes are the seventh in order of importance, and are listed before the eighth, the nose—a righteous nosology, one might add.

Loomis-Johnson, 1898, "System of Practical Medicine," under "Intestinal Neuroses," vol. iii, p. 111, article contributed by Stockton and Jones, say:

3. The conjugation of these two words, as is most common, shows that the writer has not a faint conception of the real nature of "eye-strain."

"One of the most prolific causes of functional gastric disturbances is eye-strain, and almost any neurosis may be induced by it. Gastric hyperesthesia, accompanied by hyperchlorhydria, to be followed later by more or less anasthesia and achlorhydria, seems to bear a definite relation to astigmatism of high degree. Without attempting to refer the condition to any special form of eye-strain, we have, nevertheless, been impressed with the frequency of the association of astigmatism and muscular imbalance with painful sensory conditions of the stomach, especially taking the form of distress and pain accompanied by belching after meals, with a good appetite, but voluntary starvation through dread of pain induced by eating. These patients suffer for years and are made rather worse than better by restricted diet."

Stockton, 1903, in "Nothnagel's System," American edition, article on "Diseases of the Stomach" (not in the original), comments, p. 163, as follows:

"Cases of so-called typical gastric vertigo not infrequently depend on uncorrected eye-strain, especially on anisometropia. It is true that the attacks are often precipitated by transient disturbances in digestion, and these digestive derangements in turn may be occasioned by some eye-strain that predisposes to the vertigo. In several instances I have seen the disappearance of both vertiginous and gastric symptoms follow a careful and painstaking correction of the refractive error."

Again, under "Gastric Neuroses," p. 256, he says:

"As earlier stated, eye-strain has been found a frequent cause of functional stomach trouble, especially among those who are living an indoor life and are accustomed to the close use of the eyes. This is particularly true in cases of mixed astigmatism and anisometropia, and is often associated with muscular imbalance."

Dr. Stockton has also placed himself on record more definitely and fully in the same way in an article entitled, "Hygiene of the Digestive Apparatus," in Dr. Pyle's "Personal Hygiene," issued in 1904.

Of the thousands of articles, clinical or pathologic, by physicians, that in the last dozen years have appeared in the medical journals on the subject, it may be said that, in all probability, not one has recognized or emphasized the truth set forth by Dr. Musser in the few lines quoted. It is needless to enumerate. A typical example comes to hand as I write, a solemn address by Robert Hutchinson⁴ on "Dyspepsia." Like a multitude of others, filled with light but not in the least enlightening, it is utterly oblivious of the eye-strain origin of this most common of modern diseases. No F.R.C.P. would dream of allowing such a thought to appear or even to be mentioned by him in a public way.

Thus, with the exception of one or two brief allusions in the authoritative text-books, the "scientific" medical men of the world give no hint of their "familiarity" with a highly important source and cure of the most common of all diseases. Plainly, therefore, Dr. Musser is in error as to the knowledge of the fact by medical men. This error clearly arises from the attempt to promulgate a scientific truth by a method which shall ignore the history of the discovery and "save the faces" of those who have wilfully ignored the truth discovered and fought for by others. This may be good politics, but it is unjust, and the question remains: Will it stop the ignoring and the sneering of the "conservatives?"

If, as Dr. Musser avers, eye-strain, known of all, is responsible for a large share of the disorders and diseases of digestion and nutrition, the oculists, especially of the United States, should long ago have received the truth eagerly and should have proclaimed it loudly from the house-tops and from their text-books. It is needless

to say that it is not so. I need not weary with all the negative citation of authors.

If the truth of Dr. Musser is true, the refractions of our oculists were the means of demonstrating the truth. So far as I know, only one such oculist has publicly confessed.⁵ Concerning sick headache or "migraine," many have done so, and in other essays I have given the details, quoted the writers and established the question of priority. Sick headache, however, is not the subject now under discussion. Although that disease consists in the most profound and revolutionizing morbidity of the digestive process, it presents, in the main, a different clinical picture from that of "bilious" attacks, periodical vomiting, anorexia, indigestion, and other gastric symptoms described in the quotation taken as a text.

3. The significance of Dr. Musser's statement is not recognized, and its far-reaching consequences not discriminatingly appreciated. If it is true, then the professional and the social bearings are tremendous. It may be seen at once that the practices of nearly all physicians must be thoroughly changed in the majority, or in a large minority, of the patients consulting. Not even the specialists can be excepted, because, seek where one will, do not the majority of diseases spring directly from the disorders and diseases of digestion and nutrition, or are intimately based on or associated with them? How large a portion of the drugs advertised are directly or indirectly aimed at those conditions? What is the whole nostrum, patent and proprietary medicine business but the organized attack of quackery on the demons of "dyspepsia" and denutrition? Seventeen or eighteen years of clinical observation and study have convinced me that a far larger proportion of all gastric and intestinal diseases are due to eye-strain than even Dr. Musser and Dr. Stockton would admit.

4. If I am in error, I shall be happy to be corrected, but I think I have not mistaken when I say that the recognition of the truth of the ocular origin of these diseases of digestion was begun, and for ten or a dozen years was advocated, solely by me. I care nothing personally for questions and quibbles as to priority, but I am proud of the fact that I early and long and boldly set the truth forth, and have held to it, at first in face of the silence of all others, then in spite of their ridicule and jeers. I began the crusade in 1888, publishing my first clinical report early in 1889⁶ of a case of dyspepsia of twenty years' duration cured at once by glasses. I considered attentively the clinical details and the physiologic grounds of the morbid function, its cure, etc. In January, 1890, I again gave the details of other cases, and stated that I had had in all twenty-eight patients in whom dyspepsia, anorexia, nausea, etc., were cured by the extinction of eye-strain. Later, in the same year,⁷ I again returned to the charge, giving proofs and repeating the conviction that "eye-strain produces digestive troubles of various kinds, all resulting in malnutrition, anemia," etc.

In 1891,⁸ I reported on 277 cases of digestive and assimilative disorders (anorexia, fickle appetite, consti-

5. After the above words were written, a second noteworthy exception comes to my hand, the article of Dr. Griffin, in *THE JOURNAL OF THE A. M. A.*, Jan. 6, 1906. Under "Disorders of Eye-Strain," this frank man publishes reports of cases, diseases of the digestive organs due to eye-strain and cured by ocular treatment. All honor to him.

6. *Medical and Surgical Reporter*, Feb. 9 and March 9, 1889.

7. *American Journal of the Medical Sciences*.

8. *Medical News*, Aug. 25, 1890.

9. *THE JOURNAL A. M. A.*, Sept. 19, 1891.

pation, dyspepsia, nausea, vomiting—not sick headache—car-sickness, etc.), and I wrote thereon:

"For a long time I have been begging my friends, the general practitioners, to heed the fact that digestion and assimilation may be directly and profoundly disordered by eye-strain. Nothing seems more true in medical science than this."

And much of the same purport.

Since then I have continued nearly every year to beg consideration of the fact. Not an oculist published a line of assent or seconding. At last I convinced a few of my friends in general practice, especially one great physician of national fame, by the best of demonstrations—the restored health of patients. The misfortune of the theory consists in the self-evident fact that the cures depend on an accuracy and refinement of practical refraction which has been almost impossible and unknown and which is now only becoming more general.

The manner in which the recognition of the truth is coming about illustrates so admirably the ancient psychologic way that it should be noted. Years of utter silence and ignoring follow a discovery and the repetition or re-emphasis of it by the foolhardy. Then follow ridicule, calumny, coarse dogmatism and stupid opposition of the leaders who do not lead, the authorities who are without authority, the editors who sell themselves to the *Zeitgeist* or to their commercial salary-givers, the indifferent multitude who follow blindly the blind guides. Finally, one after another acknowledge the truth, long evident to many, impossible longer to be slandered or ignored. But the distinguishing characteristic of the confession is that it is "familiar to all" and admitted by all; but still persists the death-like silence as to how the discovery was made, by whom recognition was made necessary. There is not a hint of gratitude to those who have sacrificed themselves in the cause of truth and discovery. Instead it is said: "It is familiar to all," "That is an old story," "We have always said so"—and then is renewed the custom of ignoring and maligning the new and different truth that, in its turn, is struggling for a chance to release other millions from their sufferings. "Conservatism" may be most expensive and criminal when it conserves only error.

There remain several important postscripts to be carefully considered:

1. It is evident that a breach has been made in what seemed the impenetrable walls of the professorial and authority-making classes. Heretofore all students of history and psychology have found that the real discoveries in medicine are ignored, scorned and opposed by the contemporary "authorities," the leading practitioners, the professorial and presidency seeking, the committee-forming, and the text-book-making class. Some of the men composing this class are too often too far interested in themselves, their own personal success and fame. Some are seeking to hold their dearly gained and slippery power, too occupied in courting popularity, hunting LL.D. degrees, baronetries, trusteeships, other professorships and presidencies, too desirous of doctoring the rich and those dying of organic disease, to have care for the functional diseases which, long neglected, at last land the prematurely dying in the hands of the famous consultants.

2. The question returns as to the sincerity, the effective-making and the permanency of the admission. And, first, as to the sincerity. In Dr. Musser's own text-book of last year's dating, there is but one word

out of hundreds of thousands devoted to the matter "familiar to all." In his own article from which I quote, there are some 1,400 words, of which 40 are devoted to a mere statement concerning the ocular "nongastric diseases." In the discussion of Dr. Musser's paper there were 14 participants. Their opinion of Dr. Musser's "familiar to all" admission was shown in the fact that not one considered it worth even alluding to. Now, if this is a truth of value, the matter needs to be set forth in a discriminating and serious manner. We must have the rules of diagnosis to determine the methods whereby eye-strain sets up those symptoms and how certain kinds of strain begot certain digestive diseases. We need more than all the proofs that these general practitioners and gastrologists have cured these patients. Let the cases be reported. The editors of the great official organs of their societies will print such articles from these great men, but they often refuse to do so when the little men and the hobby-riding oculists send their manuscripts.¹⁰ The editors are great friends of the "authorities." The truth is, of course, that the glittering generality, the general and vague admission, is not taken seriously; nor is it meant to be so taken.

The "familiar to all" vagueness is merely a sop thrown to Cerberus and a method of "saving one's face," so that in future years, when the despised "enthusiast and exaggerator" shall have died in establishing the contemptible truth, then those who have killed him (and their patients) by the "damning with faint praise" may proudly say, "We knew all this a generation ago and urged it and practiced it."

3. But did they know and practice it? If so, the proceedings of the great societies of oculists (through whom alone the truth could be demonstrated) and the ophthalmic text-books must show the thousandfold proofs of the theory of eye-strain as a cause of gastric diseases. With dreary monotony they absolutely omit such proofs and go on to discuss the cure, not the cause; of ocular tumors, inflammatory and surgical diseases. Of refraction problems and gastric diseases there is no curiosity or mention.

How is it in practice? Will Dr. Musser's colleagues, the great professors and text-book makers, see to it that the eyes of these patients have been accurately "glasses?" Will the leading diagnosticians and practitioners of New York, London, Paris, Berlin, Boston, Chicago, San Francisco, Philadelphia, Baltimore, New Orleans, and the rest, when a patient comes to them next week, seek to learn if there exists eye-strain? If they do this will they do more than to ask in an in-curious and humdrum way: "Have you been wearing glasses?" If they get a reply, "Yes, from a good eye specialist," will they rest unsatisfied? Do they care to go into the matter earnestly, scientifically? Do they seek to know that, as a rule, the greater the reputation of the "ophthalmic surgeon" the more certainly will his prescription of lenses be wholly inaccurate and wrong? Will they seek to learn that there are some 100 good and sufficient reasons why the glasses worn by patients generally are unscientific and incapable of relieving eye-strain? "Familiar to all" may be an astute (or blunderful (?)) way of rendering a truth unfamiliar to any.

10. At the same time the editor of the British Medical Journal accepted the MS. of Hutchinson referred to, he refused an excellent article from an English oculist showing the dependence of "dyspepsia" on eyestrain.

4. The admission, "familiar to all," may be worse than continued silence and scorn. About thirty years ago a leading practitioner wrote several articles admitting most that "the eye-strain crank" could wish, logically implying all that he now claims and giving excellently reported clinical demonstrations. He soon saw that the professional mind could not, and would not, take in the truth. It was ignored utterly and contemptuously. The promulgator realized his error and joined forever the ranks of the ignorers. About thirty-four years ago an American oculist, known of all, stated the clear truth that sick headache is caused by eye-strain. From that day to this, if I am not in error, he has never dared to repeat the hazardous admission or even to allude to it. Thus it may be seen that there are good reasons for suspecting that political shrewdness and tactical acumen often have to do with hindering the progress of medicine, and that a cunning selfishness may require that thousands of patients should continue to suffer rather than that the truth should be preached, a truth which medical dogmatism may not allow to prevail.

THE DIAGNOSIS OF RENAL CALCULUS.*

GOY L. HUNNER, M.D.

Associate in Gynecology, Johns Hopkins University.
BALTIMORE.

Few diseases present such protean symptoms and simulate such a varied array of other maladies as stone in the kidney. This is particularly true if we include in our considerations stone in the ureter.

The smallest stone may cause typical agonizing symptoms not easily mistaken even by the patient, while without attracting notice large stones may occupy both kidneys, causing insidious destruction of these organs and sudden death from anuria. In the consideration of this subject I will first discuss the diseases of the kidney which we must differentiate from calculus nephritis, and will then take up those diseases of neighboring organs which most commonly mislead us in diagnosis.

COMMON KIDNEY DISEASES TO BE DIFFERENTIATED FROM CALCULUS NEPHRITIS.

The more common kidney diseases of which we must always think in making a diagnosis of stone are tuberculosis, pyelitis, pycelonephritis and pyonephrosis from the ordinary pus-producing infections, tumor and intermittent hydronephrosis.

Tuberculosis.—At our Atlanta meeting, two years ago, I had the pleasure of reporting thirty-five cases of tuberculosis of the kidney occurring in the practice of Dr. Howard A. Kelly and his associates in Baltimore. It had been my privilege to study the urinary condition in most of those cases, and you may remember that I laid emphasis on the importance of urinary examination in making a diagnosis of renal tuberculosis. The same law holds in renal calculus—we must study the urine.

Our only positive diagnosis of renal tuberculosis is the finding of tubercle bacilli in the urine or causing the disease in guinea-pigs by the inoculation of the urine or the diseased tissues taken from the bladder. In calculus kidney the urine may show sand or a stone. The x-ray and the wax-tipped bougie are invaluable means for making a positive diagnosis, but these methods both fail at times, and if we would enjoy a full measure of success in kidney work we must insist on a careful study of the

urine. Blood occurs in the urine in both stone and tuberculosis. The amount varies in both diseases from microscopic quantities requiring both the centrifuge and microscope for the discovery of the few corpuscles present, to severe hemorrhages threatening the patient's life. The amount of blood is more likely to be influenced by exercise in cases of stone, but we sometimes have to search repeatedly before finding a few corpuscles, marking the only change in the urine. Pus in the urine, at least in microscopic quantities, may always be looked for in tuberculosis, while a large percentage of stone cases are aseptic and free from inflammatory reaction, especially in the early stages, and leucocytes, if present, can be accounted for by the amount of blood. I have found that some stone cases with only a moderate number of red corpuscles and leucocytes may have a strikingly large number of epithelial cells.

Pain as a differential symptom between stone and tuberculosis is unreliable. In either case there may be entire absence of pain. Either disease may cause only a dull backache or an indefinite nagging sensation in the lumbar region. In either disease the pain may occur in the most severe paroxysms due to blocking of the ureter by a blood clot, by a plug of detritus, or in calculus disease by a stone. At such times the kidney is likely to be enlarged and the urine may be temporarily clear.

Palpation findings in the kidney region are not characteristic, as in either disease the kidney may be smaller than normal because of atrophic sclerosis or it may be greatly enlarged from fibrosis, lipomatosis, hydronephrosis or pyonephrosis. Palpation of the ureter is of more value, as a large proportion of the tuberculous cases show thickening of the ureter after the disease is advanced in the kidney. In the infected stone cases the ureter may be thickened and simulate the tuberculous ureter. In ureteral calculus the stone is in the lower end of the ureter in 50 per cent. of the cases, and in women it can usually be palpated through the vagina or the rectum. In diagnosing a case as tuberculous on the evidence of finding acid-fast bacilli in the urine, we must always use the differential stain, as illustrated by the following case:

CASE 1.—MRS. J. B. S., aged 42, married seventeen years, the mother of two children, was admitted to Dr. Kelly's service at the Johns Hopkins Hospital in 1901. The patient had complained at intervals for the past four years of attacks of intense pain in the right lumbar region. She described the pain as labor-like in character, and said that it extended downward toward the bladder and down the thigh as far as the right knee. The attacks lasted from twenty-four hours to five days. At times they were accompanied by chills, nausea and vomiting and constipation. During the attack the patient passed but little urine, but had the constant desire, and after the attack a large quantity of urine was noticed. She sometimes had decided blood tinge in the urine during and after the attack. She never passed gravel. There was always sensitiveness in the right hypochondrium during the attacks. The patient came to Dr. Kelly with a diagnosis of renal tuberculosis, a report having been made from a state laboratory that tubercle bacilli had been found in the urine in abundance. Leonard, of Philadelphia, one of our most expert Roentgen-ray specialists, had failed to get a stone shadow. I examined catheterized specimens of urine without finding pathologic content, and the laboratory in question soon telegraphed to defer the operation, as the bacilli had been found to be smegma. At a later admission Dr. Kelly operated because of the symptoms and blood in the urine and found an oval stone about 2 cm. in length in the pelvis of the kidney.

Pyelitis, Pycelonephritis, Pyonephrosis.—It may be impossible, except at operation, to diagnose any one of

* Read at the eighteenth annual meeting of the Southern Surgical and Gynecological Association at Louisville, Ky.

these conditions from an infected nephrolithiasis. Indeed, the presence of a stone may cause any of these conditions, and again a stone may develop because of the infective process. If the history shows the trouble to have begun during or soon after one of the acute infectious diseases, or during pregnancy, or after the development of a pelvic tumor, the condition is more likely to be one of infected kidney. But we can not exclude the presence of a stone in view of such a history, for it is often under the conditions named that an aseptic stone kidney becomes infected and first begins to cause symptoms. The infected stone kidney is not infrequently the seat of such a connective tissue hypertrophy that the x-ray picture is simply a large shadow in which no stone can be outlined. This tissue hypertrophy may extend to the ureter and so close its lumen as to prevent the passage of a wax-tipped bougie into the pelvis, as happened in one of my cases.

Tumor.—It is by no means easy to differentiate between stone in the kidney and a tumor. Here, again, our chief dependence is in the examination of the urine. The occurrence of a profuse hemorrhage which begins and ceases suddenly favors the diagnosis of tumor. The presence of a persistent large tumor mass in the kidney region and the absence of pus in the urine is a combination of circumstances suggestive of tumor. It must not be forgotten that a comparatively small stone blocking the ureter may cause a marked swelling of the kidney and be associated with blood and an absence of pus in the urine.

CASE 2.—In the case of Mrs. F., June 27, 1904, I found a large tender left kidney and the urine showed considerable blood, many large epithelial cells, some unusually large, and an absence of pus. I made a probable diagnosis of tumor, but the patient refused further examination and in a few weeks passed a stone.

CASE 3.—The largest swelling of the kidney that I have ever seen was caused by the presence of an enormous stone, accompanied by fibrous hypertrophy and pyonephrosis. In examination of the urine on five consecutive days I had failed to find tubercle bacilli in the urine and considered the case one of infected tumor or nephrolithiasis. The wax-tipped bougie was negative, due, as I found after removal of the kidney with a portion of the ureter, to sclerotic thickening of the isthmus, which so narrowed the lumen that the catheter could not pass.

Microscopic examination of the kidney cortex demonstrated the presence of tuberculous disease.¹

Intermittent Hydronephrosis.—A movable kidney, in which the conditions favor the sudden kinking of the ureter, may give rise to attacks which very closely simulate renal colic due to stone. In either case there may be more or less constant discomfort in the back, with the occasional attacks of severe pain, followed by blood in the urine. If the patient is carefully watched, however, the diagnosis of Dietl's crisis is favored by finding the kidney misplaced and enlarged during the attack, and its return to normal size and position is accompanied by relief of pain and increase in the amount of urine.

Before finishing the discussion of the more common kidney diseases which may be mistaken for stone I must mention two other conditions of which I have seen a few examples. Under the designation of idiopathic hematuria or of renal epistaxis are classed those cases of renal hemorrhage for which we can find no cause even at operation. I have seen one patient who had become profoundly anemic from the loss of blood. Splitting of

the kidney in her case resulted in at least a temporary cure, although no cause could be found for the bleeding. I believe there is a tendency to-day to classify many of these cases of so-called renal epistaxis with the chronic interstitial form of Bright's disease. Acute monolateral nephritis may be even more misleading than the above condition, because, in addition to the suggestive urinary findings, we have the acute onset of renal colic.

DISEASES OF NEIGHBORING ORGANS.

Gallstones.—Because of the proximity of the gall bladder to the right kidney, we are not infrequently called on to differentiate diseases of these two organs. The urine shows blood if we are dealing with stone in the kidney and bile if there happens to be obstruction in the common duct. The pain is more likely to radiate down the ureter in the one case and to the epigastrium and up under the shoulder blade in the other. If the gall bladder is enlarged it is more superficial and has more of a pendulum movement than the kidney. Pressure over a normal liver border may be transmitted to a very tender right kidney and the symptoms be misinterpreted. Except under conditions of special technic, the x-ray does not register a shadow for gallstone.

One of the best means for differential diagnosis is that devised by Dr. Kelly of catheterizing the right kidney and forcibly injecting a bland sterile solution into its pelvis. The patient can generally tell very accurately whether the pain thus produced is similar in character and location to the pain previously suffered. If the pain caused by the injection corresponds to the patient's previous symptoms, we have simply found the location and can not say definitely that we are dealing with nephrolithiasis. An unusual amount of blood after injection is suggestive of a pelvis already injured by stone. If the wax tip returns with scratch marks, we are certain of stone in the kidney or ureter. If the pelvis holds an unusual amount (the normal pelvis takes in woman 120 mm., 7.5 c.c., or 2 drams, before the patient complains of a fullness or discomfort), there is a dilatation which we have found due to various conditions, viz., stone in the kidney or ureter, movable kidney, stricture of the ureter, and tumors of the pelvic organs pressing on the ureter.

The following case, after the kidney investigation, was considered to be one of probable gallstone irritation:

CASE 4.—Mrs. A., aged 63, the mother of several children, was operated on at the Johns Hopkins Hospital in 1897 for acute appendicitis with abscess formation. The drainage wound became the site of a hernia, for which she was operated on in 1900. I saw the patient with Dr. Finney in July, 1904, at the Union Protestant Infirmary. She had been complaining for about six weeks with an indefinite nagging pain in the upper abdomen, more on the right side. She had had no stomach or bowel trouble, no fever or jaundice. There had been some soreness at times over the right hypochondrium. On examination there was general tenderness over the upper right quadrant of the abdomen. We thought of gallstones and of an ommentum adherent to the laparotomy wound in the lower part of the abdomen, and causing the symptoms by tugging on the mesentery of the hepatic flexure of the transverse colon.² A specimen of urine catheterized from the bladder contained a few pus and epithelial cells. No red corpuscles were noticed. On cystoscopy I found the bladder reddened in areas, and considered these changes sufficient to account for the few pus and epithelial cells found in the urine. Wishing to exclude stone in the right kidney, however, I catheterized this organ with a wax-tipped bougie with negative results. The urine

1. "The Significance of the Urinary Examination in Women," Southern Surg. and Gyn. Transactions, 1904, Case 2, p. 489; also Amer. Med., 1905, vol. ix, p. 559.

2. Hunner: "An Interesting Complication in the Diagnosis of Gallstone," Am. Med., 1903, vol. v, p. 698.

from this kidney contained no pus and the slight amount of blood present was attributed to the trauma of catheterization. About three weeks after this catheterization the patient had her first severe attack of renal colic, passed a small stone by the urethra, and has since enjoyed good health.

Appendicitis.—It would seem to the casual observer that disease of the appendix could not be easily mistaken for renal calculus. But we must remember that many appendix attacks are accompanied by little or no elevation of temperature and that the pain may be located in the kidney region. If we include in this discussion stone in the ureter, we can readily understand that the diagnosis may become more complicated. The ureteral stone may be lodged on the brim of the pelvis and give local pain and tenderness almost exactly under McBurney's point. On the other hand, an inflamed appendix may reach over into the pelvis and cause bladder and rectal symptoms, and, on palpation through the vagina or rectum, the peri-appendicular tenderness and thickening may be mistaken for signs of stone in the ureter. The urine is our safest guide in such cases, but I have recently had a most remarkable case in which I was completely misled because of the urine examinations.

CASE 5.—Miss R., a trained nurse, aged 26.

History.—For ten years she had complained of attacks of pain in the right side, with a more or less constant pain in the region of the right kidney. I saw the patient in consultation with Dr. Julius Friedenwald in December, 1904. She had had two severe attacks within four weeks, requiring hypodermics of morphia for each attack. The attacks, which usually lasted several hours, began with throbbing in the rectum. This increased to a severe pain in the pelvic region and was followed by pain in the region of the right kidney. With some attacks there had been pain in the bladder. At times there had been vomiting. She had never been jaundiced. She stated that the pain never began in the kidney region, radiating downward. There was no very marked soreness anywhere after the attack was over. A number of the attacks had been followed by the passage in the urine of large amounts of pus and blood. After one of these attacks the urine was catheterized from the bladder and sent to one of the most careful microscopists in Baltimore. He found both pus and blood.

Examination.—At my first examination the urine catheterized from the bladder was absolutely normal. A wax-tipped bougie passed to the right kidney returned negative, and the x-ray picture was negative. The patient was very stout and I felt that the x-ray might easily fail to cast a shadow, particularly if the stone were small and of porous formation. While the symptoms pointed to a pelvic location of the primary trouble, I felt that the negative wax-tip was almost positive evidence that the ureter contained no stone, and yet the urine findings after the attacks had been so positive that I considered the case one of urinary-tract disease.

Operation.—I began the operation by exposing the kidney and splitting it from end to end. The kidney was large, and indentations on the surface appeared like scars. No stone being found in the pelvis of the kidney, nor palpated in its substance, I closed this organ with mattress sutures of catgut and explored the ureter as far as the pelvic brim. The lumbar wound was then closed, except for slight drainage to the kidney cortex, and, turning the patient to the dorsal position, I made an extraperitoneal inguinal incision and explored the ureter from the pelvic brim to the bladder, with negative results. I then opened the peritoneum and found an hypertrophied inflamed appendix, which, reaching over the pelvic brim, was densely adherent over the ureter. The right ovary was so firmly attached to the peritoneum over the pelvic ureter that I was obliged to free it by scissors dissection. I can explain her attacks of renal pain and hemorrhage only on the supposition that the appendicular inflammation was communicated to the ureter, causing a temporary stenosis of this organ, with acute hydronephrosis and evidence of kidney inflammation. A section of the kidney cortex taken from one of the scarred-looking

areas showed a mild grade of interstitial infiltration with areas of glomerulonephritis. The patient, whose attacks had been increasing in frequency, has been perfectly well since the operation.

Intestinal Obstruction.—Occasionally an attack of renal or ureteral stone colic causes a reflex paralysis of the bowel, with its attendant meteorism and obstipation. If the attack is accompanied by rectal tenesmus, nausea and vomiting, the picture is still more confusing.

CASE 6.—Mrs. K., aged 61, seen with Dr. Eldred at Sparrows' Point. The patient was taken five days ago with sudden pain in the left flank region. She has had several attacks each day, the attacks being more marked between midnight and 6 o'clock in the morning. Dr. Eldred at first considered the attacks due to stone in the kidney or ureter, but as he was unable to get the bowels moved, and as the intestinal distention and distress grew more marked, he began to fear intestinal obstruction. A catheterized specimen of urine was very dark colored. Unfortunately, I did not have a good microscope at hand and did not determine whether there was blood in the urine. The bowels were moved on the day of my visit, and about one week later the patient passed a cylindrical stone about 1 cm. long.

Pancreas Stone Colic.—Recent work by Opie and others has demonstrated conclusively the intimate relationship between gallstones and pancreatic disease. One would scarcely mistake the typical case of acute hemorrhagic pancreatitis, with its sudden onset of acute colicky pains in the epigastrium, nausea and vomiting, subnormal temperature, or chills and fever, and especially when accompanied by the early onset of severe collapse symptoms, for a case of renal calculus. But the mistake might easily be made in the more chronic cases of pancreatitis. The history of former attacks of indigestion or typical gallstone colic, the location of the pains, the presence of a pancreatic tumor, are all helpful differential points. In the future many cases will be differentiated by the examination of the urine, the kidney-stone cases showing blood, while sugar will be found in the pancreatic cases.

Henoch's Purpura and Angioneurotic Edema.—Both of these conditions are often marked by attacks of gastrointestinal crises and renal hematuria, a combination of symptoms that might easily lead to a diagnosis of renal colic caused by stone.

CASE 7.—L. F. Jewess, aged 20, married. I saw this patient immediately after her admission to the Hebrew Hospital on March 19, 1905. She was flexed almost double by epigastric pain, which two quarter-grain hypodermics of morphia had failed to relieve. The husband said that she had such attacks about once a month. I suspected gallstone colic, and on examination found that another surgeon had anticipated my diagnosis. The husband explained that the linear scar in the right hypochondrium had been made at the City Hospital one year before and that gallstones were not found.

I then instructed the resident physician to examine carefully a catheterized specimen of urine, as he would almost surely find blood as an evidence of stone in the kidney. As I turned to leave, the wife found her Yiddish tongue and the husband said, "Oh, yes, doctor, please look at the lump on her leg." Situated over the upper end of the left tibia was an oblong elevation of the tissues, measuring about 4x6 cm., purple in color, the color disappearing from local areas on pressure and slowly returning. Knowing Dr. Osler to take a special interest in visceral crises in purpuric conditions, I asked the resident physician to notify him of the case. "Yes, yes," said the husband, "she has been in the Hopkins Hospital several times." By referring to the hospital records I found that she had been admitted repeatedly because of attacks similar to the present one. With some attacks she had nausea and vomiting and epistaxis. "Black and blue" spots had been mentioned by the family, but subcutaneous bleeding had not been seen at the hospital, and the diagnosis had always been entered as "re-

curring attacks of abdominal pain." The urine during and immediately after these attacks showed a trace of albumin and hyaline and granular casts, but no blood.

In this cursory and superficial view of the subject I have hoped to throw out enough suggestions to convince you that the diagnosis of stone in the kidney is often a very difficult problem, to be solved generally by a process of exclusion. In closing I recall a sentence from Israel's introduction to his chapter on the diagnosis of kidney-stone colic. He says, in effect, that if one would place himself in a position to diagnose other cases than those with the typical symptom-complex he must, first of all, divest himself of the schematic picture so often presented in the text-books.

A CASE OF TRAUMATIC ENDOCARDITIS.

A. HERZFELD, M.D.

NEW YORK.

Our knowledge of traumatic endocarditis is still very imperfect, though many valuable contributions have been added to our literature since George Fischer¹ published his excellent monograph on this topic.

The following case recently came under my observation, and as I had the opportunity of observing it from its very beginning until its end, a period of nearly two years, I consider it of sufficient interest to publish it.

History.—Albert S., aged 9, always enjoyed fair health. There was no syphilitic, tubercular or rheumatic history in the family. At the age of two the patient had measles and subsequently several attacks of acute bronchitis. No tubercular element in these attacks was noticed.

During the winter of 1902 the patient contracted a light attack of pneumonia, which lasted about one week and left him rather weak. Mucons rales could be heard over both lungs for several weeks after the attack. During his entire illness pulse had always been normal and of good quality. The heart sounds and area of heart dullness were normal. Examinations of urine showed a specific gravity of 1012 and no pathologic constituents.

Examination.—On June 8, 1903, while running, the patient fell violently on his chest. He immediately became unconscious, and two hours after the accident I found him still suffering from profound shock. His face and extremities were cyanotic and covered with a cold perspiration. Respiration was superficial and rapid, temperature subnormal. Pulse small and fast, 170 to 180, of very low tension.

On inspection the whole left side of the thorax appeared to be pulsating, the heart action was so rapid and tumultuous that it was impossible on auscultation to differentiate between systole and diastole. A loud murmur could be heard over all the valves, but its time relation to the heart cycle could not be clearly made out. It seemed to be a continuous murmur. The region of the chest, bounded by the right border of the sternum, the middle axillary line, the third rib below and the epigastrium below, was pulsating so violently that the heart action was plainly visible at a distance. The heart dullness corresponded with this area of visible pulsations. The apex beat appeared to be between the anterior and middle axillary lines in the seventh intercostal space. On the next day, when I saw the patient in consultation with Dr. I. Adler, his general condition and heart action had not changed. No fluid was found in the pericardium. Patient had partially regained his consciousness, but was still very apathetic and listless.

Treatment.—The treatment consisted in the application of the ice bag over the heart and internally five drops of tincture of opium every two to three hours. On the third day one drop of the fluid extract of digitalis every two to three hours was added. As the patient could not stand the pressure of the ice bag we resorted to icy cold water applications. Under this treatment the acute symptoms subsided, and the fourth

day after the injury the heart action became more regular; the pulse now was 140, small and easily compressible. A loud blowing systolic murmur could be easily heard over the region of the apex beat, which was transmitted to the left and behind. The heart sounds over the aortic, pulmonary and tricuspid valves were not quite clear, but no murmur could be heard the digitalis treatment was continued, but the dose was reduced to one drop three times a day.

Further Examinations.—On June 28 the boy was allowed to sit up in bed. A careful examination of the heart on that day still revealed the same loud systolic murmur over the mitral valve. The sounds over the other valves were perfectly clear and normal. The digitalis treatment was continued one to two drops a day and when, after an extended absence from the city, I saw the patient again on Oct. 25, 1903, I found his general condition much improved, pulse 120 and his heart smaller. In addition I could now hear a loud diastolic and faint systolic murmur over the aortic valve which were not present at the time when I left the patient in June. I did not see much of the patient during 1904, as he had been taken to the country apparently improved. I saw him again on Jan. 4, 1905, when he showed the signs and symptoms of an influenza. During the attack the heart again became insufficient, and fluid extract of digitalis was again given. The most prominent symptoms during this influenza attack was the very marked dyspnea. Patient improved again and on Feb. 27, 1905, I showed him at a meeting of the Society of German Physicians of New York. At that time he was pale, anemic and poorly nourished. He was restless, easily excited and for a few weeks had showed distinct choreic movements. Nothing abnormal could be discovered in the lungs, but on deep respiration the lower intercostal spaces were drawn in. The heart impulse was easily visible, its pulsation could be seen extending from the right border of the sternum to the anterior axillary line. The apex beat was most distinct in the sixth intercostal space between anterior and middle axillary line. There was a distinct pulsation in the epigastric region. The heart dullness extended from the third rib above to the apex beat below and from the anterior axillary line to the right border of the sternum. Over the apex a loud blowing systolic murmur could be heard, which was transmitted to the left. Over the aorta a loud systolic and diastolic murmur could be made out. A systolic murmur was also heard in the carotid, sub-clavian, axillary, brachial and femoral arteries and a distinct murmur on either side of the vertebral column extending from the lower end of the scapula to the first lumbar vertebra. The carotids pulsated visibly. The pulsation of the capillaries could be seen under the finger nails (Quincke's capillary pulse). The second pulmonary sound was accentuated. Nothing abnormal was found over the tricuspid valve. There was no venous pulse. A systolic thrill could be felt over the entire heart area, particularly over the left ventricle. Pulse was 120 and of a low tension. The blood pressure, according to tonometer of Gaertner, was 70-80 mm. The liver was distinctly palpable about two fingers' breadth below the free border of the ribs. The spleen could also be palpated under the free costal margin. The urine of a specific gravity of 1018 showed a slight trace of albumin, but no casts. No edema or ascites was noticed. Eyesight was apparently normal. Patient complained of frequent attacks of dyspnea, palpitation of the heart and extreme weakness.

Further Treatment.—On April 20, 1905, I was called to see the patient. His heart's action was identical with that observed right after the original injury. A very severe dyspnea was present, pulse 160 to 170, heart's action very rapid and tumultuous. He told me that another boy hit him and he had to run away from him. I again ordered the cold applications to heart and gave him internally two to three drops pure tincture of opium every two to three hours. The cardiac insufficiency was very marked and the whole left side of the thorax seemed to pulsate. The insufficiency of the heart became more apparent from day to day. Face and extremities were cold and cyanotic. Digitalis and hypodermic injections of strychnin finally had no more influence on the heart's action and on May 2 patient died. On account of religious scruples the autopsy was not permitted.

¹ Geo. Fischer: "Die Wunden des Herzens und des Herzbeutels," Archiv. f. klin. Chir., vol. ix, 1868.

LITERATURE AND DISCUSSION.

This interesting case induced me to look up the literature of similar cases in order to compare them with mine and to study their mechanism and the changes produced in the anatomy of the heart.

How a traumatism in the shape of a fall or any other violent contusion inflicted on the thorax affects the heart muscle has been for years a matter of serious consideration and research and the opinions of the different authors vary greatly.

Maclaure² claims that all such injuries to the heart are due to hydraulic pressure and that the resultant injury will vary according to whether the heart at the time of the trauma was in systole or diastole. He claims that these severe contusions always cause "*une véritable anévrisme cardiaque*."

Schmidt³ explains the injury to the heart caused by blunt violence, by the mechanical pressure of the blood column itself in the aorta. The blood pressure being suddenly increased by the injury may be sufficient to tear the valves, when immediately after the diastole the artery is filled to its maximum and the valves are closed. Under such favorable conditions, he claims that even a mild concussion may cause serious injury.

Ebbinghaus⁴ does not share this theory, and he thinks that the elastic fibers in the wall of the artery will sufficiently compensate for the shock.

Baric⁵ claims that the severe compression of the thorax at the time of the injury caused in turn a sudden backward pressure of the blood against the valves and may burst these. All authors agree that any violence which causes a compression of the thorax also increases seriously the blood pressure in its interior, particularly in the arteries.

After these general remarks let us analyze my case. At the time of the injury the boy was rather weak, having gone through a number of attacks of acute bronchitis and a light attack of pneumonia, but his heart, muscle as well as valves, had always been in normal condition. The pulse and urine were normal. I do not think that the repeated attacks of bronchitis and above mentioned pneumonia had a serious influence on his myocardium, as he never showed any signs of a disturbance in the circulation. He had no temperature at the time of the injury—this will exclude any acute ailment, nor did he have any increase of temperature after the injury. The injury to the heart and the endocarditis following it could not have been caused by anything else but the trauma, because immediately afterward the previously apparently healthy heart showed the severe clinical affection described above. As the trauma did not cause the least injury to the wall of the thorax itself nor any visible injury of any kind, we must assume that we had to deal with a so-called *contrecoup* injury to the heart. One of the most striking features of my case was the enormous dilatation of the heart, but there was no tear in the heart muscle itself, no fluid could be detected in the pericardium by either Dr. Adler nor myself. The extent of the dilatation did not change very much during the entire two years, and the compensation of the heart muscle itself was never well established.

Ebbinghaus⁴ claims that the acute dilatation of the heart muscle itself may cause a tear in the endocardium,

even when there is absolutely no injury to the bony framework of the thorax, which, being elastic, yields, but the heart muscle not yielding, causes a *contrecoup* tear in the endocardium. In all cases where the heart muscle has been injured by blunt violence the valves are most frequently affected, and even a perfectly sound valve may be seriously injured or ruptured, as demonstrated by Baric⁵ in experiments on the cadaver and by cases published by Foster⁶ and Schmidt³.

The left ventricle, valves and muscle are much more liable to injury than the right, but the rupture of the muscle seems to be more frequently met with on the right side. Baric's⁵ statistics of thirty-eight cases show injury to the aortic valve nineteen, mitral valve sixteen, and tricuspid valve three. Of all the valves the aortic is most frequently injured. The injuries to the mitral valve consist mostly in the tearing of the chordae tendineae or of the papillary muscles. The valve itself is rarely implicated. In Baric's sixteen cases of mitral injury mentioned above an autopsy was made in fifteen cases and nine showed the tearing of the chordae tendineae, five the tearing of the papillary muscles, in one case both lesions were present, none, however, showed a tear in the valve itself. These injuries always cause an insufficiency of the valve. In my own case the mitral and not the aortic valve received the full force of the violence at the time of the accident, as the murmur, which could be heard soon after the injury, was a loud systolic one, heard most distinctly over the apex and transmitted to the left. Nothing could be heard over the aorta after the *delirium cordis* had somewhat subsided on the third day. Similar cases have been reported by Stokes and Townsend.⁷ In these cases the autopsy revealed a tearing of the chordae tendineae of the mitral valve.

The injuries of the endocardium are usually followed by endocarditis, which develops in consequence of the injury to the valves or any other part of the endocardium (Rosenbach⁸). Many authors think that the so-called traumatic endocarditis most frequently causes stenosis of the valves, but a careful study of the literature leads me to believe that we meet just as many insufficiencies.

In my own case the traumatic endocarditis caused primarily an insufficiency of the aortic valve and the stenosis followed the insufficiency. In October, 1903, four months after the accident, I detected, for the first time, a loud diastolic murmur of the aortic valve. The systolic sound was muffled, but a distinct murmur could not be heard. The systolic murmur developed gradually, and at the time of the demonstration of the patient in February, 1905, the two aortic murmurs were of the same intensity. The primarily developed insufficiency soon caused stenosis by verrucous granulations forming on the diseased valve and narrowing the lumen of the ostium. This pathologic process has been described by C. Gerhardt.⁹

The origin of traumatic endocarditis has been also a subject of great dispute. Litten¹⁰ and many others claim that the injury to the endocardium provides a convenient nidus for micro-organisms, which in turn cause the above mentioned verrucous granulations on the valve and stenosis.

Traumatic endocarditis frequently develops slowly and insidiously, so that we may speak of a latent period or a period of incubation. The patient may suffer very little during this period, and, therefore, does not seek medical advice until new complications arise. In this way it may happen that a traumatic endocarditis, although of longer standing, may not be detected until some time after the injury. Any cause which requires more work of the already injured heart muscle, as an intercurrent disease, another traumatism, psychic excitement or muscular exertion, would result in a lack of compensation and cause the patient to consult a physician. The latent period or period of incubation may last weeks, months or even years, as in a case recently reported by Prandi.¹¹

It is very hard to know what anatomic changes had taken place in the myocardium of my own patient, as an autopsy was refused. I do not doubt that there were considerable changes, as after the injury the heart muscle was never able to perform its normal function and the periods of improvement were always only of short duration. Furthermore, it has been shown by various authors that even the slightest injury to the muscular fibers of the heart or the smallest hemorrhage in the heart muscle, resulting in a separation of the ultimate fibrils, will cause disturbances in the sense of a myocarditis.

The choreatic movements described above are also of interest; they developed some time after the traumatism and continued throughout the entire illness of my patient. I could not find a similar affection described in the literature on this subject.

Finally, I desire to express my thanks to Dr. I. Adler for the kind interest he has taken in the preparation of this paper.

RESULTS OF FACIO-HYPOGLOSSAL ANASTOMOSIS FOR FACIAL PALSY.

ALFRED S. TAYLOR, M.D.

Visiting Surgeon to the New York City Children's Hospitals; Assistant Instructor in Operative Surgery, College of Physicians and Surgeons (Columbia); Clinical Assistant in Surgery New York Hospital, Out-Patient Department.

NEW YORK.

A description of the surgical technic as well as the histories in three cases of facio-hypoglossal anastomosis appeared in the *Medical Record* of Feb. 27, 1904. These cases were presented before the Surgical Section of the New York Academy of Medicine in January, 1904.

Because of the short postoperative period—four, three and two months, respectively—no results had appeared at that time. As each of the three has developed motor power on the paralyzed side, the interest of the cases perhaps justifies a second report, even though the return of power is not complete. Moreover, four additional cases have been operated on. There has not yet been time for the return of motor power, but there are in each case points of considerable interest when compared with the preceding series.

In general terms, the operation consists in dividing the facial nerve at its exit from the stylo-mastoid foramen, exposing the hypoglossal nerve behind the internal jugular vein and above the level of the posterior belly of the digastric muscle, and, finally, in doing a lateral implantation of the distal portion of the facial nerve into a longitudinal slit in the hypoglossal. The junction is wrapped with Cargile membrane or other material to prevent the ingrowth of connective tissue into the field of the anastomosis. While this last step of the procedure was mentioned in the publication to which reference has been made, its importance was not sufficiently accentuated. To this precaution is probably due a large share of the return of power in Case 1, as will be noted later.

Another most important factor in obtaining results lies in the after-treatment. The systematic use of electricity and massage are naturally very important for maintaining the muscular tone and nutrition. Electrical stimulation, moreover, is said, by the most recent observers, to promote greatly the fibrillation of the axicylinders, in which consists the final stage of nerve regeneration. With the first evidence of returning motor power in the paralyzed muscles comes the time for the introduction of the most important single element in the after-treatment, i. e., the systematic exercise of graded voluntary motions in the muscles of the paralyzed side of the face.

There is no doubt that the strongest stimulus to the morphologic and physiologic regeneration of nerves which have been sutured lies in the transmission (or attempted transmission) of volitional impulses from the cortical centers.

Moreover, it must not be forgotten that the transplantation of a distal motor nerve trunk to some neighboring motor trunk removes it from the control of cortical centers which have been educated to the necessities of the coordinate activities of its muscles to new centers which are ignorant of the requirements of its muscle-field. There is, then, an evident primary necessity for the re-education of the new cortical centers to their new duties.

This process is slow and accounts for the fact that emotional symmetry, which is the highest development of coordination, is the last thing to appear in the return of control, and that the return of coordinate power requires so much longer time proportionately than in cases of end-to-end suture of the same nerve trunk.

Basing his technic on this consideration, one surgeon entirely divided the hypoglossal trunk, with consequent permanent paralysis of its muscle-field, and did an end-to-end suture of its proximal stump with the distal portion of the paralyzed facial nerve, hoping thereby to get a more rapid and complete return of power by limiting the activity of the hypoglossal cortical center entirely to its control of the facial muscle-field.

It is hoped that the results reported herewith will give such evidence of surplus activity in the hypoglossal centers as to render this procedure unnecessary.

The first three cases referred to are the ones reported in the *Medical Record*.¹

CASE 1.—History.—J. M., aged 6, had scarlet fever in the early summer of 1903, followed by otitis media and mastoiditis on the right side, for which an operation was done July 13 at

1. The photographic records in the early cases are very incomplete because of the difficulty of getting a photographer, the patient and some one to pose the patient all together at one time; the failure of certain amateur attempts; and a lack of appreciation of the value of certain poses.

11. Prandi: "Di un endocardite traumatica latente," *Gazz di osp Milan*, 1903, vol. xxiv, p. 502.

Randall's Island Hospital. Three days later, beginning facial palsy appeared and rapidly progressed to complete paralysis. Three and one-half months later complete R. D. was found on electrical examination.

Operation.—On October 24, 1903, under chloroform anesthesia, operation disclosed the facial nerve soft, friable and gray in appearance; slight traction on it with the thumb forceps drew it out of the stylo-mastoid foramen without the necessity of dividing the nerve. (This fact was not stated in the previous report, but is recorded in the original notes on the case.) Two lateral sutures were inserted to implant its end in the slit in the hypoglossal. One of these pulled out through the substance of the facial nerve after both sutures had been tied, and not enough nerve was left to attempt to insert another.

four months the face was symmetrical during quiescence (Fig. 3). The muscles still showed R. D.

From this time there has been steady but slow improvement. Very slight voluntary movement appeared first at the corner of the mouth eight months after operation (Fig. 4). One year after operation the motion in these muscles was very distinct and much increased (Fig. 5). The tongue still protruded to the right side (Fig. 6), but less than immediately after operation (Fig. 2), and it could be voluntarily moved in all directions. The right side was distinctly smaller than the left. The patient was not conscious of any discomfort. Thirteen months after operation the eye could be almost completely closed and the corner of the mouth drawn well out toward the right ear (Fig. 7). These motions could also be done sepa-

Fig. 1.—Case 1. Before operation. Complete paralysis of right side of face.

Fig. 2.—Case 1. After operation, one week, showing deviation of tongue to right side.

Fig. 3.—Case 1. Four months after operation, showing symmetry of face during quiescence.

Fig. 4.—Case 1. Eight months after operation, showing beginning of voluntary movement at right angle of mouth and return of naso-labial fold.

As there was considerable tension on the remaining suture, a catgut suture was passed through the sheath of the hypoglossal nerve below the anastomosis, and then through fascia, so that when it was tied the hypoglossal was pulled up and outward, thus relieving tension at the anastomosis, which was still, of course, very unsatisfactory. Cargile membrane was wrapped about the junction and the wound closed. Primary union resulted.

Subsequent History.—There was almost complete palsy of

the muscles supplied by the hypoglossal immediately after operation (Fig. 2). The resulting interference with phonation deglutition and mastication lasted for many weeks, although after ten weeks it had ceased to be annoying. The right side of the tongue, while it has regained its full range of motion, has always remained somewhat smaller than the left side (Figs. 6 and 10). Because of the unsatisfactory anastomosis the prognosis as to return of power in the facial field was distinctly unfavorable. However, systematic after-treatment was carried out with the following results: At the end of ten weeks there was distinctly less asymmetry of the face and at

the muscles supplied by the hypoglossal immediately after operation (Fig. 2). The resulting interference with phonation deglutition and mastication lasted for many weeks, although after ten weeks it had ceased to be annoying. The right side of the tongue, while it has regained its full range of motion, has always remained somewhat smaller than the left side (Figs. 6 and 10). Because of the unsatisfactory anastomosis the prognosis as to return of power in the facial field was distinctly unfavorable. However, systematic after-treatment was carried out with the following results: At the end of ten weeks there was distinctly less asymmetry of the face and at

At twenty-five months, improvement is still continuing. The laugh is more nearly symmetrical (Fig. 11). Power to elevate the upper lip is greater. (Compare Figs. 11, 12, 13, 15 with 2, 8 and 9.) Power to elevate the lower lip has appeared (Fig. 13). The frontalis is beginning to act slightly (Fig. 15). The corrugator supercilii is stronger (Fig. 16).

CASE 2.—History.—B. G., aged 45, in August, 1903, had severe pain in the right ear for two days, followed by complete paralysis of the right side of the face. Electricity, massage and

baths systematically used for three months elicited no evidence that power would return spontaneously. R. D. persisted in the muscles from the beginning.

Operation.—On Nov. 28, 1903, under ether anesthesia, anastomosis was made without any tension on the sutures. Primary union resulted.

Subsequent History.—Following operation, there was paralysis of the muscle field of the right hypoglossal nerve (Fig. 17). The tongue protruded to the right side and there were difficulties of speech, mastication and deglutition, as in the preceding case. After six weeks these difficulties had disappeared, although the tongue remained smaller on the right side (Fig. 18). For nearly two months this patient complained of moderate intermittent pains in the shoulder, neck and external ear of the right side. These were probably due to injury to the auricular branches of the cervical plexus during the operation, the pain being referred also to other branches than the ones injured.² Six weeks after operation, although R. D. still persisted, there was a distinct diminution in the amount of constant current which it was necessary to pass through the anastomosis to cause contraction in the facial field. Two weeks after operation the tongue deviated markedly to the right side, could not be voluntarily moved to the left, and the right side was noticeably smaller and more wrinkled. The paralysis of the face is evident from the staring eye, the absence of wrinkles on the right side as compared to the left, and the absence of the naso-labial fold on the right side (Figs. 17 and 18). Four months after operation (Fig. 18) the tongue protruded almost straight and had regained nearly normal range of motion. The face at rest had largely regained its symmetry and the naso-labial fold had reappeared. The opening of the mouth and protruding tongue prevent it from showing in the photograph.

Six months after operation (Fig. 20) a considerable amount of voluntary motion had returned at the angle of the mouth and somewhat less in the right palpebral region. This side could be worked independently of the other. Note the diminished palpebral fissure. When an attempt was made to use both sides of the face at once, to show the teeth (Fig. 19), the left side was so much stronger as to pull the right side over and reproduce an appearance of paralysis.

After six months the patient disappeared and has been lost to observation in spite of repeated efforts to trace her. From the progress made in six months it is probable that her present showing would be very satisfactory, especially since the major part of her improvement occurred between the fourth and six months of the time that she was observed.

CASE 3.—L. M., aged 26, had complete right facial palsy following a mastoid operation done eighteen months previously. There had been no spontaneous improvement.

Operation.—On Dec. 22, 1903, Dr. Weir, assisted by Dr. Taylor, performed the operation, using ether anesthesia. The operation went smoothly and was followed by primary union. Paralysis of the hypoglossal muscle-field and the pains complained of by B. G. (case 2) followed operation in this case, but disappeared after a number of weeks.

Further Remarks.—This patient came very irregularly for after-treatment, and about three months after operation moved out of the city. In January, 1905 (thirteen months after operation), she reappeared for inspection. Although she had entirely neglected the instructions as to after-treatment, the result was still pretty satisfactory, as indicated in the photographs (Figs. 21 and 26).

In this case swallowing was accompanied by a slight grimace of the right side of the face, correlated motions analogous to those of the face and shoulder in facio-spinal accessory anastomosis.

Figure 21 shows the face in natural pose before operation; Figure 22, the degree of closure of the eye; Figure 24, taken thirteen months after operation, shows the return of symmetry during repose, with normal naso-labial fold and frontal wrinkles (compare Fig. 21); Figure 25 shows

the power to close completely the eye and retract the right side of the mouth (compare Fig. 22); Figure 26 shows separate control of the right side of the mouth and face; Figure 23 shows recovery of the tongue from its paralysis and the power to protrude it well over to the left side.

In all three cases paralysis of the hypoglossal muscle-field was an immediate sequel to the operation and persisted for a number of weeks. This was undoubtedly due to traumatism inflicted on the hypoglossal at the time of operation. To minimize this injury a set of special instruments was designed³ and used in the later cases with very satisfactory results.

CASE 4.—*History.*—Mrs. M. J. had had complete facial paralysis (Bell's palsy) of the left side of the face for twelve years, with the deformity shown in Figures 27 and 28. There was marked atrophy of the muscles. There was some reaction to the galvanic current at the left corner of the mouth. (Complete R. D.) The left eye was painful on continued use, and there was increased lacrimation with an annoying overflow on to the cheek.

Operation.—On Jan. 7, 1905, under ether, the usual operation was done and the nerves were approximated without tension. Although the palsy had existed twelve years, the trunk of the facial nerve appeared normal in size, color and consistency. A small segment was taken for microscopic examination. This was the first case in which the special instruments were employed, and after operation the patient had none of the hypoglossal palsy which was so annoying in the preceding cases. There was numbness of the left ear, and some of the pains noted in the preceding cases were experienced. The wound healed by primary union.

Subsequent History.—Seven weeks after operation the face felt different and more comfortable than it did before operation. Lacrimation was distinctly less annoying and the eye was less troublesome. The patient and her friends thought that the face was becoming more symmetrical and that the eye could be more completely closed, but a careful inspection failed to verify that fact.

Fifteen weeks after operation the asymmetry was slightly lessened and the patient felt that the face was stronger. During the last few weeks of that period there has developed a slight but distinct atrophy of the left side of the tongue, so that it protrudes somewhat to the left involuntarily. Nevertheless the patient can move it in any direction at will. Five months after operation slight dimples could be formed in the chin voluntarily, but a successful photograph was not gotten till eleven months had passed. By this time the lower lip could also be slightly elevated (Fig. 31).

After a palsy lasting twelve years, so early a return of power, though only slight, promises much for the final result.

CASE 5 (referred by Dr. W. C. Phillips).—Miss I. C., aged 26, strictly speaking, can not be classed as an illustration of a case of facio-hypoglossal nerve anastomosis, but the attempt to do the operation developed certain facts that make it worth reporting in connection with the other cases.

History.—For twelve years this young woman had suffered from mastoid disease and had had some five operations. After one of the operations for an acute exacerbation eight years ago there appeared a complete facial palsy of the right side which has persisted. Also during one of the exacerbations several years ago there had developed a diffuse cellulitis of the upper part of the neck, which left a cicatrix covering the upper third of the right side of the neck. There was a small sinus back of the auricle leading into necrosed bone.

Operation.—The attending otologist requested that the nerve anastomosis should be done immediately after he had removed the diseased bone, in order that one anesthesia should answer for both purposes. After a careful cleansing of the field the usual operation for the anastomosis was started. After a painstaking dissection, which lasted an hour, involving exposure of the stylomastoid foramen, it became evident that the trunk of the facial nerve was not present. Moreover, the upper

2. In Case 6, where this nerve was retracted instead of divided, these pains did not appear.

third of the sternomastoid muscle was lacking. It, therefore, seemed probable that the diffuse cellulitis above referred to had caused the destruction of the nerve and muscle. The operation was abandoned.

Inasmuch as the patient had been under the anesthetic for two hours, it did not seem wise to attempt any modification of the operation, but in a similar case under favorable circumstances it would seem reasonable to attempt to expose the facial branches in the posterior part of the parotid (assisted by a needle electrode), and, if they were found, to reflect a portion or the whole of the hypoglossal or spinal accessory nerve and do an end-to-end suture.

CASE 6 (case referred by Dr. L. L. Mial).—John L. E., aged 19, had a complete left facial palsy after a mastoid operation which was done five and one-half months previously. The palsy was first noted twenty-four hours after operation and became complete forty-eight hours later. After the third month there seemed to be some slight improvement about the eye, but it was of short duration, and for six weeks before operation there was absolutely no progress; there was complete R. D., and the consulting neurologist gave an absolutely bad prognosis.

Operation.—On Feb. 14, 1905, operation was performed under ether anesthesia. The transverse process of the atlas was more than twice as large as usual and caused a distinct rounded prominence of the soft parts behind the angle of the jaw. This anomaly (which was bilateral) rendered the later steps of the operation exceedingly difficult. The great auricular nerve was identified and retracted instead of being divided as in the preceding cases. The facial nerve was readily identified. Around it and compressing it for a distance of a centimeter from the stylomastoid foramen was dense cicatricial tissue from which it was dissected with some difficulty and then it was divided at the stylomastoid foramen. This cicatricial compression would have caused a persistent palsy. The hypoglossal was exposed as usual, but because of the anomaly above mentioned it lay at the bottom of an unusually deep and narrow hole. The anastomosis was finally completed after much difficulty and considerable traumatism to the hypoglossal. The operation lasted two hours.

Subsequent History.—The patient reacted well and primary union resulted. From the considerable operative traumatism to the hypoglossal it was expected that a well-marked paralysis of its muscle-field would result, but happily this did not occur. There was a very slight degree of deviation of the tongue to the left, but it could be moved in all directions voluntarily. There was but slight disturbance of phonation and deglutition. There was loss of sensation in the upper part of the auricle. He returned home on the fifth day. Ten months have elapsed and there is no evidence of returning power.⁴

CASE 7 (case referred by Drs. Ducl and Ledermann).—Ancert L., aged 28, had a complete left facial palsy following a mastoid operation in January, 1905. After eight and one-half months there was no evidence of returning power, and, as the probability was that the nerve had been divided at the mastoidectomy, nerve anastomosis was decided on.

Operation.—On Oct. 14, 1905, under ether anesthesia, part of the lower facial canal was removed and the nerve divided. Even so it was somewhat shorter than was desirable. The anastomosis was carried out in the usual manner, except that no Cargile membrane could be wrapped about the junction. The operative result could be classed only as fairly satisfactory.

Postoperative History.—The recovery was good and primary union resulted. The day after operation the tongue deviated slightly to the left and there was slight interference with swallowing. A week after operation the tongue could be voluntarily moved in all directions, although its left side looked somewhat smaller than the right. One month after operation the excessive lacerimation of the left eye, which had been present before operation, ceased, and the left side of the face "felt different and stronger." Ten weeks after operation

the face looked very slightly less asymmetrical. The tongue, while smaller on the left side, is freely movable in all directions. The diminished lacerimation and improved facial symmetry indicate a probably favorable result.

In the third, fifth and sixth cases there was considerable cicatricial tissue below the mastoid tip surrounding the facial trunk after its exit from the stylomastoid foramen. To identify and free the facial nerve under these conditions is a delicate and tedious task. In future similar cases it would seem a more certain and rapid procedure to expose the facial nerve in the lower part of its canal by removing some of the mastoid bone and then to follow the identified nerve through the cicatricial tissue to the parotid gland.

In other cases where the facial trunk is short, later experience teaches that to expose the lower part of the facial canal by the removal of the overlying bone is the quickest and surest way of obtaining a proper length of facial trunk. The amount of bone removed is small and there is no resulting deformity.⁵

RESULTS.

Immediate.—1. Mortality absent and shock very slight.

2. A well-marked paralysis of the hypoglossal nerve was present in the first three cases, with disturbed phonation and deglutition. These disturbances disappeared after from six to ten weeks, though moderate unilateral atrophy of the tongue persisted.

In the fourth, sixth and seventh cases the evidence of hypoglossal damage was very slight and showed only by the least deviation of the protruded tongue to the paralyzed side.

3. Each case healed by primary union. The scar was small and not very noticeable.

Remote.—1. A moderate hemiatrophy of the tongue has persisted in Cases 1, 2 and 3, though in each case the power to move the tongue in all directions has returned and the patients are conscious of no inconvenience. In Cases 4 and 6 after three months and in Case 7 after two months there appeared some atrophy of the tongue on the paralyzed side, but without loss of voluntary control or sensible inconvenience to the patient. The explanation of this delayed atrophy is not yet clear.

2. Voluntary motion to a very satisfactory degree has returned in Cases 1, 2 and 3. In Case 1, because of the unsatisfactory conditions found at operation, but little was to be hoped for, and yet by faithful attention to the details of after-treatment the patient has made such progress in twenty-five months that nearly complete return of power is to be expected ultimately (Figs. 1-16).

Case 2 made rapid progress toward the return of power between the fourth and sixth months, after which time she disappeared from observation and could not be located again (Figs. 17-20).

Case 3, without paying any attention to after-treatment, came back at the end of thirteen months with a considerable return of voluntary control over the face (Figs. 21-26).

Case 4, though paralyzed for twelve years and with badly atrophied muscles, yet showed beginning return of power around the chin and corner of the mouth at the end of five months, and this power is steadily, though slowly increasing and extending (Figs. 27-32).

4. In reading the proof of this article, we are able to add the following memorandum: February 12, one year after operation, the patient was seen again. Distinct voluntary motion has appeared in muscles of chin, lower lip and about the angle of the mouth.

5. Dr. Chas. H. Frazier of Philadelphia, and Dr. A. B. Ducl of New York each made this suggestion in conversation with the authors.

Case 6, at the end of ten months, had not shown any return of voluntary power (but see Footnote 4 in this connection).

The improvement in the face after the nerve anastomosis follows certain interesting lines. First, the patient notices, in from three to six weeks, that the eye of

those cases where the muscles have markedly atrophied during a prolonged palsy. During this period the strength of galvanic current required to cause contraction in the facial muscles when the electrode is placed over the nerve anastomosis steadily decreases.

Third, in from five to eight months, voluntary motion

the paralyzed side feels more comfortable and that laceriation is less annoying.

Second, in from six to twelve weeks, the patient and friends notice that the face is less asymmetrical in repose and, in from three to five months after operation, almost perfect symmetry in repose is present, except in

appears, first about the corner of the mouth and in the chin, and then later extends to the muscles above, involving, last of all, the eyebrow and forehead muscles. It is worthy of note that improvement continues over a very long period of time. After twenty-five months

Case 1 is still adding to the number of muscles as well as the range of motion under his control.

The results thus far reported by various authors (see footnote on page 862) place the relief of facial palsy by nerve grafting among the standard surgical procedures.

DISCUSSION OF METHODS.

The chief questions open to discussion relate to (a) the choice between the spinal accessory and the hypoglossal nerves as the source of new power for the facial; (b) the choice between the end-to-end suture of the

spinal accessory nerve was used, but since that time most operators have turned to the hypoglossal as a more satisfactory source of power.

In all the "accessory" cases noted, there have been associated movements between the shoulder and the face

muscles which have resulted in unsightly grimaces and distortions. Ballance and Stewart and some others report that, after a long interval of time, patients can dissociate the two groups of movements by persistent effort and re-education of the cortical centers. This objection, therefore, is somewhat less valid than it was primarily supposed to be.

During the last three years the hypoglossal has chiefly been used to innervate the facial because of the more intimate relations, both anatomic and physiologic, of their centers in the cortex, as well as in the medulla. Moreover, the muscle fields of these two nerves are most intimately correlated in their activities.

The advantages, indicated by these theoretical considerations, seem to be derived in actual practice from the use of the hypoglossal nerve, if one judges by a comparison of the reported results in the two series of cases. Moreover, Ballance and Stewart, who report the largest number of "accessory" anastomoses, state that in future they shall use the hypoglossal nerve.

The theoretical considerations certainly would seem to favor transverse section of whichever nerve is chosen, followed by end-to-end suture of its proximal stump to the distal portion of the paralyzed facial. One would expect a more rapid and complete nerve regeneration and a corresponding improvement in the muscle-field. Moreover, the period of re-education of the cortical centers would be presumably diminished, since they would attend only to the demands of one muscle-field, instead of dividing responsibility, as they do in cases of lateral implantation.

However, in the cases reported, the results have shown no material advantages in favor of the end-to-end suture, which, on the contrary, has certain decided drawbacks. Whether the accessory of the hypoglossal is used, there is complete and permanent paralysis of the corresponding muscle-field. When the accessory is used, the trapezius and sternomastoid or trapezius alone (according as the whole or only the trapezius portion of the nerve is divided) are paralyzed, soon atrophy, cause drop shoulder and a marked asymmetry which is especially conspicuous in women wearing low-cut gowns.

Where the hypoglossal is cut, the difficulties with phonation, mastication and deglutition noted in the early weeks of our cases must become permanent, although the patient may so adapt himself to his new conditions as to avoid much of the discomfort incident to his disability. To justify itself, this method must show very distinct advantages over others in results, and, as previously stated, it has failed to do so in the cases reported up to date (January, 1906).

On the other hand, the lateral implantation method causes the minimum of additional damage to the patient, and the results have been very satisfactory in nearly every case (see especially Figs. 1-16). The technical difficulties of this operation are slightly greater.

To those who prefer the transverse section, followed by end-to-end suture, the suggestion is made (Taylor) that the distal end of the accessory or hypoglossal, whichever may be used, be anastomosed by lateral implantation into the nearest spinal motor nerve root. This would add but little to the time and difficulty of the operative procedure and would save the corresponding muscles from permanent paralysis.

(c) The interval of time which should be permitted to elapse between the onset of paralysis and the operation is the subject of wide diversity of opinion among authors.

The minimum interval mentioned is four months (Spiller and others), while many think that at least a year should elapse. Other things being equal, everyone must agree that the early operation has all the advantages. The one reason for conservatism is the great possibility of spontaneous recovery. Until the study of a large number of cases shall give us a method by which an early prognosis may be arrived at with a considerable degree of precision, there can be no scientific basis for the selection of these cases for operation.

For present purposes an interval of a year might be allowed, for by that time returning motion would have appeared in the vast majority of cases where spontaneous recovery would occur. In cases where the nerve is divided and perhaps a segment removed, as in gunshot injuries, operative procedures, etc., obviously the anastomosis should be done at once.

On the other hand, there is no fixed time during the course of a paralysis after which nerve anastomosis is contraindicated, for cases are reported where returning power has followed anastomosis after the paralysis has persisted from twelve to twenty-nine years. As long as the paralyzed muscle tissue has not completely atrophied and entirely changed to connective tissue there is a possibility of success.

In every case, regardless of other considerations, both before and after operation, the paralyzed muscles should be kept in the best possible condition by means of massage, electricity, etc., in order that returning nerve power may find good muscle to work on.

Rest in Inflammation.—Physiologic rest is of infinite importance and is always indicated in acute inflammation. In the exercise of function blood is taken to a part and an existing inflammation is aggravated.—Brainard, in *Journal Michigan State Medical Society*.

A CLINICAL STUDY OF MIXED INFECTION IN TUBERCULOSIS.

PRELIMINARY REPORT.*

F. M. POTTENGER, A.M., M.D.

AND

CHARLES C. BROWNING, M.D.

Medical Directors of the Pottenger Sanatorium for Diseases of Lungs and Throat.

MONROVIA, CAL.

One of the many debatable questions in tuberculosis is that of mixed infection. Some observers account for nearly all elevations of temperature which pass beyond a very moderate limit as being due to a mixed infection. Others, on the contrary, question whether the advent of other bacteria into the field of tuberculosis has anything to do with the production of the fever, even that of the hectic type.

Many bacteria besides the tubercle bacillus are found in tuberculous sputum. The various pus organisms, especially the streptococci, are commonly present. That these various organisms are found in the sputum is not sufficient ground for associating them with the tuberculous process, for they may have come from the mouth, throat or other portions of the respiratory tract. To obviate this possibility of error Pfeiffer¹ suggested that the particles of sputum for examination be taken from the center of the mass of sputum. Kitasato even went further and washed the sputum mass in sterile water before the sample for examination was taken.

Other observers, as Petruschky,² Fraenkel³ and Schroeder and Naegelsbach,⁴ examined the blood to see if it contained the organisms. These examinations usually proved to be negative. It is only rarely that the various organisms mentioned in connection with tuberculosis are found in the blood, and when found it is usually in the blood taken after death, and it is highly probable that they passed into it during the hours immediately preceding death.

Still other observers, as Ortner,⁵ Sata,⁶ Schabad,⁷ Cornet⁸ and Kitasato,⁹ made cultures from the walls of cavities after the death of the patient. In some instances these cultures were taken almost immediately after death, to prove that the organisms were there during life and that they had not come from other parts of the air passages after the death of the patient.

This method revealed about the same varieties of organisms as were found by the examination of the sputum. The pus organisms, especially streptococci, were most commonly found. Staphylococci, pneumococci, influenza bacilli and pseudo-diphtheria bacilli were pres-

ent less commonly. In some instances no other organisms than the tubercle bacillus were found.

The important fact to be borne in mind in these observations is that these various organisms were found not only in the air passages and cavities present, but also in the lung tissue beyond; some, as Ortner, even noting them in the tissues which had not yet been invaded by the tubercle bacillus.

Some idea of the frequency with which other organisms associate themselves with the tuberculous process may be gained from the following: Ortner found an organism which he named micro-coccus-pneumoniae, but which later proved to be a streptococcus in twenty-eight out of forty-two examinations. Pasquale¹⁰ found streptococci in the sputum every time in eighty-two cases. Schroeder and Mennes,¹¹ in twenty-one cases of tuberculosis in all stages, made thirty examinations of sputum and found streptococci twenty-nine times, staphylococci seventeen times and pneumococci fifteen times.

The important question to decide is what part these various organisms, which are found in so large a percentage of the cases of advanced tuberculosis, play in the pathologic processes present.

The mere presence of these organisms in the sputum, cavities and tissues of the lung does not prove that they play a part in the destructive process; however, the clinical picture of what is usually termed a well defined case of mixed infection, with its chills, "hectic" temperature, profuse sweats and general prostration, is similar to that of a severe streptococcal infection. The various culture products made from the tubercle bacillus will produce, for the most part, these same symptoms, and this makes it very difficult for us to decide whether the severe symptoms accompanying so-called mixed infection are due to the tubercle bacillus or the accompanying organisms or to a combined action of the two. The necrosis and liquefaction which accompanies the tuberculous process could also be produced either by the tubercle bacillus alone or by other organisms or by a combination of them. Some claim that the destruction produced by the tubercle bacillus and its toxins is always a dry process, and that when we find a purulent discharge it shows that pus organisms, especially streptococci, have entered the field; while others, as Meissen,¹² say there is not a single symptom or condition present in so-called mixed infection that could not be produced by the tubercle bacillus alone. Those of us who have had considerable experience with the use of tuberculin and other culture products and have had the opportunity to study the physiologic effects of this remedy, as seen in the tuberculin reaction, can readily believe this statement. There is some difference, however. When we have a tuberculin reaction the patient experiences aching of the limbs, back and head, more or less severe, which closely resembles the symptoms accompanying la grippe and which is not so common in cases of so-called mixed infection. There is also a certain nervousness accompanying and preceding this aching which is not usual in the so-called mixed infection.

Having had considerable experience with tuberculin, we were inclined to lay little stress on the effect of other bacteria, and believed that the hectic fever of phthisis, with its accompanying symptoms, the same as that of less degree, was due to the absorption of the tox-

ins of the tubercle bacillus together with certain products of destroyed tissue.

In the winter of 1903 our attention was called to the beneficial effect of streptolytic serum in cases of streptococcal infection, and it was determined to use it in cases of so-called mixed infection in phthisis to see if it would have any effect on the temperature. Its use was limited to cases in which the streptococci were found in the sputum, taking the sample according to Pfeiffer's method, after having had the patient rinse the mouth thoroughly before furnishing the sample. Ten patients in all were treated and the serum was advised in two other cases in consultation. The serum was used subcutaneously, usually beginning with 20 c.c. and following with 10 c.c. a day. In several of these cases the injections were continued until the streptococci disappeared from the sputum, while in others they were stopped on account of the severe reactions which followed. In some instances the urticaria was very severe; in others severe pains manifested themselves in the joints, while in still others purpura developed. In one case a cyanosis appeared and a fatal outcome was feared, but after a few hours the patient was restored to her normal condition and no bad effects seemed to follow.

These results were very encouraging, in spite of the severity of the accompanying symptoms. When the treatment could be carried out for a satisfactory period there was a diminution, and in several instances an entire disappearance of the streptococci. Simultaneous with the disappearance of the streptococci in several instances there was an abatement of the symptoms. The fever lowered, the chills ceased and the patient began to improve. There was a change in the character of the sputum in all cases. It became thinner, less in amount and less purulent in character. In some cases, in spite of the diminution and disappearance of the streptococci, the symptoms did not abate. In these cases we were inclined to believe that perhaps the continuation of the fever was due either to the toxins of the tubercle bacillus or the absorption of necrotic tissue.

This experience led us to believe that this remedy had a specific action on streptococci. While all our patients were not relieved of their troublesome symptoms, yet there were sufficient successes to be more than suggestive of the value of the remedy. The great drawback to its administration, however, was the severe reaction manifested by such conditions as urticaria, pains in the joints and purpura. On this account we ceased using it until we learned that it could be given by the bowel. Since then we have taken up its administration again.

Certain investigators, as Ortnér, Cornet and Spengler, demonstrated that streptococci are found not only in the sputum and the cavity contents, but also within the lung tissue beyond the areas of necrosis. It was also found that the association of these bacteria was not always productive of temperature.

The following questions suggested themselves:

1. Are the symptoms accompanying so-called mixed infection due to the presence of other organisms, especially the streptococcus, as is generally believed?

2. If the streptococcus is responsible for these symptoms it must be present before they manifest themselves, and would it not be the part of wisdom to treat mixed infection before these threatening symptoms appear?

3. If the streptolytic serum is active against the streptococcus, by its administration in cases where streptococci have not been found in the sputum, or in cases where they might be found, yet are producing no symptoms commonly attributed to them, we might be able to

demonstrate whether or not there is an early mixed infection without marked symptoms and also to gain some idea as to what part the streptococcus plays in the pathology of the disease.

In order to throw light on these important questions we have carried out a series of experiments on twenty patients at the Pottenger Sanatorium for Diseases of the Lungs and Throat. The injections were all given by the bowels and produced no inconvenience, except in one case there was some soreness of the finger joints. We hope to carry on our investigations during the coming year, but believe that our results so far warrant this preliminary report. We make it in the hope that it may stimulate others to investigate this important subject. A study of the varieties of streptococci which complicate tuberculosis shows them to be of very low virulence. The use of cultures from these sources might produce a serum which would be more active against these low-grade cocci than that produced by the ordinary virulent germ, and we would suggest its trial.

The results of our use of the serum are shown in the table. In presenting these cases we will state that those who had been in the sanatorium for a period of time before beginning the use of streptolytic serum had received such treatment as had seemed to be indicated, and during the administration of the serum in all cases such other treatment was administered as seemed best. The serum was administered to all cases daily, *per rectum*, between and including the dates given.

In selecting cases all excepting the last two in the table had a temperature range of 100 or more.

The twenty cases reported herewith were selected from ninety-seven cases under treatment in the sanatorium from March 20 to August 1, 1905, and included the most unfavorable as regards final recovery, although some of those which terminated fatally were most pronounced in responding to the action of the serum by showing amelioration of the symptoms attributable to the streptococcus.

The findings by the microscope have been disregarded in this report. Streptococci were found in the sputum in a number of cases before beginning the use of the serum and were not found subsequently, but the investigations were undertaken depending solely on clinical data.

Believing that streptolytic serum does have at least a certain degree of specific action in streptococcal infection, we endeavored to note the effect on the symptoms and clinical course of the disease which followed its administration. It will be noted that in nearly every case there was a change in the sputum. It became thinner, less purulent and usually diminished in amount. Some of our cases had been in the sanatorium for some time, but were not doing well; others were cases which had just been admitted, but were in bad condition. We had hoped to try it also on favorable cases, but did not in these experiments. There was an improvement noted in the general condition of 17 or 85 per cent. of those treated.

It might be argued that this improvement was due to the hope aroused by the treatment, but such was not the case, for many of the patients had been under treatment and had had many things done for them; others positively objected to the treatment because of the annoyance, while none knew what we expected to accomplish, so the mental stimulus can safely be eliminated.

The administration of foreign serum has some stimulating properties and will sometimes aid the organism in throwing off the disease and might have had some influ-

CASES ILLUSTRATING USE OF STREPTOLYTIC SERUM.

Brief History, Time of Admission.	General Condition Beginning Use of Streptolytic Serum.	Time Serum Used and Dose.	Results.
Case No. 1.—Admitted Mar. 3, 1905. Third stage involvement; extensive areas in both lungs, also involvement of larynx, pharynx and digestive tract. Temperature range to 104. Symptoms of marked general infection.	Some amelioration of severe symptoms; temperature range less; expectoration less in quantity; continued tenacious and purulent; temperature 102.5.	Mar. 20 to Apr. 2, 10 c.c.	Expectoration somewhat lessened in amount and raised with less effort; temperature range slightly decreased; some apparent amelioration of general symptoms. Patient discharged unimproved.
Case No. 2.—Admitted Jan. 9, 1905, in advanced stage; both lungs involved.	Condition of lungs improved; temperature range continued to go above 100 at frequent intervals; expectoration profuse and tenacious.	Apr. 15 to May 3, 10 c.c.	Sputum became thinner and lighter in color; less purulent; range of temperature less; general condition improved. Patient discharged improved.
Case No. 3.—Admitted Feb. 22, 1905. In advanced stage.	Had shown practically no improvement since admission.	Apr. 15 to May 20, 10 c.c.	Condition of patient during stay at sanatorium improved but slightly.
Case No. 4.—Admitted February, 1901. In second stage, also lupoid involvement of anterior nares, extending to upper lip, soft palate, pharyngeal wall, epiglottis and arytenoids.	Had treated since admission with culture products and violet rays. Susceptibility to culture products very marked. Temperature range above 100 frequently; condition of lungs and lupoid patches much improved.	Apr. 15 to Apr. 17, 10 c.c.	Swelling and aching of joints manifest. Serum discontinued.
Case No. 5.—Admitted Mar. 18, 1905. Second attack; marked involvement of upper portion of both lungs and intestinal tract; temperature 103.	Marked improvement; temperature range above 100 frequently; expectoration profuse and tenacious.	Apr. 15 to May 3, 10 c.c.	Expectoration thinner, less purulent and less in quantity; subsequent improvement more rapid.
Case No. 6.—Admitted Feb. 10, 1905. Advanced stage in lungs and intestinal tract.	Improvement of general symptoms; temperature range above 100; expectoration profuse and tenacious.	Apr. 15 to May 3, 10 c.c. May 8 to June 6, 10 c.c. June 7 to July 30, 20 c.c.	Sputum decreased, became thinner and less purulent. Following use of serum the first time, there was marked general improvement, which continued for several days, when it was again used with more marked improvement. Following its use the third time with larger dosage, improvement was still more marked and continuous.
Case No. 7.—Admitted Feb. 25, 1905. Involvement of both lungs; previous history of severe pleuritis with effusion; infiltration arytenoids.	Had made marked improvement since admission; severe attack of pleuritis and effusion, left side, developed.	May 3 to May 25, 10 c.c. May 6 to June 5, 10 c.c. June 21 to July 5, 20 c.c.	Amount of sputum markedly decreased, thinner and less purulent. General condition much improved.
Case No. 8.—Admitted May 5, 1905. Advanced stage, both lungs; temperature had been ranging as high as 105; expectoration profuse and purulent from large cavities; general symptoms of severe infection.	Marked improvement; temperature above 100 at frequent intervals; expectoration profuse and tenacious.	May 23 to June 20, 10 c.c. June 20 to June 27, 20 c.c.	Expectoration decreased, thinner and less purulent; general condition improved more rapidly than before administration of serum; maximum temperature 99.5.
Case No. 9.—Admitted Mar. 31, 1905. Had been treated the year previous with marked improvement; large cavity in left lung, also involvement of right lung; larynx involved.	Marked improvement in general symptoms; temperature still 100 to 101 almost daily.	May 22 to June 7, 10 c.c.	Expectoration less in amount and less purulent; rapid amelioration of all symptoms; general improvement until June 7, when severe hemorrhage occurred, followed by death one week later.
Case No. 10.—Admitted May 16, 1905. Advanced stage, both lungs; extensive fibrosis; high range of temperature, reaching frequently 104.	Marked improvement in general symptoms; temperature still 100 to 101 almost daily.	May 27 to June 20, 20 c.c.	Rapid improvement of all symptoms, including diminution in quantity of sputum and lessening in its offensive character. June 20 a cavity formed in left lung; general re-infection. Patient died three days later.
Case No. 11.—Acute tuberculosis; temperature ranged as high as 105; other symptoms of very virulent infection; large cavity in right lung and involvement throughout both lungs, larynx and intestinal tract; expectoration purulent, exceedingly profuse and offensive.	Had made marked improvement under treatment, range of temperature 100 to 101 at frequent intervals.	May 28 to June 20, 10 c.c. June 20 to June 28, 20 c.c. June 4 to June 20, 10 c.c. June 20 to June 29, 20 c.c.	Amount of expectoration markedly decreased; less purulent and less tenacious; temperature range lower and general condition improved.
Case No. 12.—Admitted May 16, 1905. Advanced stage; temperature 104.2; general condition showed marked infection.	Condition improved; range of temperature from 97 to 99.5; expectoration profuse, purulent and tenacious.	June 11 to June 23, 20 c.c.	Sputum less in amount and less purulent; temperature range lower and improvement more rapid after beginning use of serum.
Case No. 13.—Admitted Aug. 30, 1904. Advanced stage.	Condition improved; range of temperature from 97 to 99.5; expectoration profuse, purulent and tenacious.	June 14 to June 30, 20 c.c.	Sputum less in amount, thinner, less purulent and raised with less effort; temperature range lower; symptoms generally ameliorated. June 30 tubercular meningitis supervened; death in thirty-six hours.
Case No. 14.—Admitted Mar. 10, 1905. Advanced stage; temperature 98 to 100.	Condition improved; range of temperature from 97 to 99.5; expectoration profuse, purulent and tenacious.	July 7 to Aug. 1, 20 c.c.	Expectoration less in amount, thinner and less purulent; temperature range lower; improvement in general condition slight.
Case No. 15.—Admitted June 13, 1905. Advanced stage; both lungs involved; extensive infiltration and ulceration of pharynx, larynx and arytenoids; also involvement in digestive tract; temperature range 101.2; expectoration profuse, heavy and purulent.	Condition improved; temperature range 98 to 103.8; expectoration profuse, purulent and tenacious.	July 7 to Aug. 1, 20 c.c.	Expectoration less, thinner, less purulent; general condition much improved.
Case No. 16.—Admitted July 1, 1905. Extensive involvement of both lungs, long standing; extensive fibrosis; temperature range 99 to 102; expectoration profuse, tenacious and purulent.	Condition improved; temperature range below 100; expectoration profuse, very tenacious and purulent.	July 29 to July 30, 20 c.c.	Expectoration less in quantity, thinner, less purulent; reduced temperature range.
Case No. 17.—Admitted July 20, 1905. Third stage involvement, both lungs, also larynx; temperature 103; expectoration profuse, tenacious and purulent.	Condition improved; temperature range below 100; expectoration profuse, very tenacious and purulent.	Apr. 15 to May 3, 10 c.c. May 28 to June 20, 10 c.c. June 20 to June 8, 20 c.c.	Expectoration following first administration reduced in quantity, thinner and less purulent; same condition noted following its use the second time; more marked following increased dose; improvement continuous.
Case No. 18.—Admitted Aug. 19, 1904. Third stage involvement, with cavities, upper lobe, both lungs.	Condition improved; temperature range below 100; expectoration profuse, very tenacious and purulent.	July 8 to July 23, 20 c.c.	Expectoration less in quantity, thinner and less purulent; general condition showed marked improvement and has since continued.
Case No. 20. Admitted Dec. 27, 1904. Advanced stage, also laryngeal involvement.	Conditions of both lungs improved; slight improvement of larynx; expectoration profuse, tenacious and purulent; temperature range 98 to 99.		

ence on the general improvement, but it could hardly be expected to have influenced in so marked a degree the character of the expectoration. It seems to us that such an influence can come only through some specific action on the elements productive of the expectoration.

From our studies and observations we would draw the following conclusions:

1. The results of various investigations show that streptococci are found in lung tissue beyond the areas of necrosis, and can be present without causing any acute symptoms, such as high fever, chills, etc.

2. The products of the tubercle bacillus are capable of producing symptoms very near, if not identical, with those of so-called mixed infection, and it is possible that these are sometimes due to the one cause, sometimes to the other, and perhaps at times to both working together.

3. That the streptococcus plays a part, at least in some cases of so-called mixed infection in tuberculosis, and that streptolytic serum has at least some specific action on the streptococcus as witnessed in the reduction of fever and abatement of symptoms in some of these cases of hectic type, and further, that the streptococcus plays some part in the general pathology of the tuberculous process of these chronic cases without marked symptoms (the earlier ones we have not yet investigated) as is shown by the altered character of the sputum, becoming thinner, less purulent and diminished in amount, and in the general improvement which follows the administration of the serum in nearly all cases.

4. The use of streptolytic serum in cases where no acute symptoms were present seemed to exert a favorable influence on the course of the disease sufficiently often to suggest that the presence of the streptococcus affects the tuberculous process unfavorably, even in many cases where it causes no active symptoms, and that mixed infection is a factor to be recognized and dealt with, before the advent of threatening symptoms, the same as tuberculosis is to be diagnosed and treated before the advent of consumption.

5. This field is worthy of further study and investigation, and while we do not feel justified in drawing any absolute conclusions, we feel that our results so far warrant a continuation of our investigations.

AUTOLYSIS.

P. A. LEVENE, M.D.

NEW YORK.

(Continued from page 778.)

Before concluding the review of the products resulting from proteid cleavage in the process of autolysis mention has to be made of the formation of plasteins. From the foregoing discussion it is apparent that great activity has been displayed in the study of degradation of the proteid molecule within the body and in the test tube, and an attempt has been made to explain the bearing the work had on our understanding of various physiologic functions. However, there was one great problem which inspired many workers in their labors and which remains unsolved by them. This was to discover a process by which proteid, the chief tissue component, could be constructed out of its simple components, and also to discover the mechanism which the organism employs to build up tissue proteid out of those fragments which are formed in the digestive tract. It has been stated before that the first phase in proteid digestion consists in converting native proteid, which is insoluble in boiling water, into products which are

soluble both in hot and cold water. These products are termed albumose and peptone. Danilewski and his pupil, Okneff,¹⁹ were the first to make the observation that when the soluble substances are exposed to the action of rennet ferment a substance arises which is insoluble in water. This substance was termed plastein. Kurajeff,¹⁵ another student of Danilewski, has shown that the plasteins are formed by the action of autolytic enzymes also. It has been shown in recent years that enzymes possess a double function. They break up complex into more simple substances and again rebuild the original substances from the fragments. Hill made this observation on the enzymes digesting starch, and Kastle and Lowenhart²⁰ on that spitting fat. The first ferment is capable of converting sugar into starch and again starch into sugar; the second possesses the power of converting fat into fatty acids, and the acids into fat.

Attempts were made to ascribe a similar faculty to enzymes digesting proteids, and the plasteins were regarded by many investigators as reconstructed native proteid. The most emphatic supporter of this theory was Herzog.²¹ He based his assumption on a very ingenious experiment. The viscosity of a dilute of native proteid decreases in course of digestion. On the other hand, the viscosity of a fairly concentrated solution of albumose exposed to the action of digestive enzymes increases. This, according to Herzog, may be explained by the reconstruction of proteid. However, if the digestive action of the enzyme is disturbed by the presence of an antiferment, the reconstruction fails. Very recently Kurajeff and his pupil, Grossman,²² exposed digested plasteins to the action of autolytic enzymes and noted the formation of coagulable proteid, and they seem inclined to believe that this indicates a reversible action of the autolytic enzymes. Unfortunately the experiments of various writers on the subject contain many contradictions. While the primary albumoses are considered the mother substance of plasteins by some writers, Kurajeff noted the formation of plastein only from the secondary ones. Further, Bayer,²³ in Hofmeister's laboratory, found that plastein is formed from crystalline cleavage products.

In our own experiments, Stookey and I failed to find any evidence of reconstruction of the lower albumoses into coagulable proteid. By the action of rennet ferment on albumose it was possible to convert the solution into a solid jelly, which was very difficult to fractionate for purely mechanical reasons. If, for the experiment, a solution of albumose of moderate concentration was employed, it turned into a very thick syrup. In the original solution and the one treated with rennet the various albumoses were estimated. The time of treatment with rennet varied from 12 to 48 hours. In no instance was there observed any diminution in the quantity of the lower albumose or of the peptone. Thus there was no evidence of reversion of peptone into coagulable proteid, and it is extremely improbable that enzymotic synthesis of proteid can be made possible before the substances at present known as proteolytic enzymes are divided into their components. Cleavage of proteids by trypsin, pepsin or other proteolytic enzymes is a very complex process. Reversibility of action thus far is known to be a property of enzymes affecting a hydrolytic cleavage. In the course of proteid

disintegration in the tissues and in the digestive tract, the primary products so rapidly suffer further metamorphosis that reversion on a large scale is scarcely imaginable. There might be other synthetical processes to which the organism resorts for the purpose of tissue construction.

It has already been stated that special attention has been directed to the study of the products of autolysis of nuclear material. Through the work of Fischer, it was established that the components of nucleic acid were closely related one to another and all of them, in turn, related to uric acid. In addition, the pathogenesis of many diseased conditions, and particularly that of gout, is closely associated with uric acid. Normally fresh organs contain the components of nucleic acid in a free state only in a very insignificant quantity. Schutzenberger, Salomon and Lehmann (the last working under Kossel) observed that yeast suspended in water and allowed to stand at body temperature gave rise to free nucleic bases, the fresh cells not containing the substances in a free state. Salkowski and his pupils, Schwiening and Biondi, made it certain that the appearance of the substances was due to an autolytic process. More recent investigations have made it clear that through autolytic action purin bases, as soon as they become detached from the complex molecule of nuclein, suffer complete decomposition. Statements to that effect were made by earlier observers, more recently by Kutscher. The observation of Dakin²⁴ is in harmony with this statement, although he could detect in autolyzed kidneys only one purin base, hypoxanthin. The correctness of the statements was demonstrated by my own investigations. Quantitative analysis of all purin bases present in the fresh and in autolyzed organs has made clear the destruction of nucleic bases in the course of self-digestion. Very recently also some information has been gained regarding the chemical process of their disintegration.

In living tissues only adenin and guanin are present in large quantities, while the other two purin bases are found in very insignificant quantities. Walter Jones²⁵ and I,²⁷ independently of one another, have shown that in the course of autolysis, these two bases are transformed into hypoxanthin and xanthin, respectively. The following table shows the contents of purin bases in 5 pounds of fresh and autolyzed spleen:

	Fresh spleen.	Self-digested spleen.
Adenin	1.85 gm.	0.0 gm.
Guanin	1.19 gm.	0.0 gm.
Hypoxanthin	0.30 gm.	1.2 gm.
Xanthin	0.40 gm.	0.150 gm.

Schittlhelm arrived at similar conclusions and has demonstrated further that under certain conditions the bases are transformed into uric acid. The other constituents of nucleic acid, the pyrimidin bases, undergo analogous changes.

The mechanism of this transformation was elucidated by the work of Jones.²⁵ This author accepts the presence in the tissues of two specific enzymes, one capable of acting on guanin and the other on adenin, and further of an oxidizing enzyme, the function of which it is to complete the transformation of nuclear material. The deductions of Schenck²⁶ are similar to those of Jones. Schittlhelm²⁹ has corroborated in a general way the conclusions of Jones. However, he does not support the assumption of the existence of more than

one enzyme which can transform the amino-purins into the corresponding oxy-derivatives. According to Schittlhelm, the entire nuclear destruction is accomplished by three enzymes, one breaking up the nucleic acid into its components, the second splitting off the nitrogen from the nitrogenous constituents, and the third completing the oxidation of the purin derivative. It must be admitted that more detailed information concerning the intermediary products of nucleic metabolism is still wanting.

With this I wish to conclude the review of the products arising on autolysis of surviving organs. Reference should be made to the products of autolysis of sugar and fat, but thus far the investigations in that direction are few in number and the results obtained from them not very significant. This also concludes the review of autolytic action in normal organs. It remains to discuss these results in connection with the original problems which led to all these numerous investigations.

DISCUSSION OF RESULTS.

It has been stated already that the principal object of the work was: 1. To elucidate the nature and the mechanism of those chemical reactions which make the functions of the body possible. 2. To interpret the rôle of individual organs in the animal metabolism. 3. To study the intermediate products of metabolism, since there is a general agreement that by the accumulation in the organism of these substances many diseased conditions are occasioned.

The foregoing review leads one to the conclusion that the knowledge of intermediate metabolism has been furthered considerably. On the other hand, a comparative study of the products of disintegration of various organs fails to bring out marked differences among them, although, during life at least, some organs are known to be the seat of special chemical reactions. This leads one to the assumption that in the animal body the process of self-digestion does not control all chemical reactions occurring in organs, perhaps even not all the processes of disintegration. A most conspicuous instance illustrating this statement is found in the work in which Eck's fistula was employed. By this name is designated a fistula between the vena cava and the portal vein. The aim of the fistula is to exclude the liver from the portal circulation. The organism of the dog possesses a very intense power of burning uric acid; the acid is present in the urine of this animal only in traces, even after injection of two to three grams of the substance. Dr. Sweet and I have demonstrated that animals kept for weeks on a diet free from all precursors of uric acid excrete considerable quantities of it in the urine as soon as an Eck fistula is performed on them. The output is especially increased after the administration of the substance itself.

Evidently under these conditions the organism fails to disintegrate uric acid, although the process of self-digestion is not depressed in the tissues. Thus the mechanism of "burning" uric acid in the living organism is not known yet. Proteid combustion also in the normal living organism apparently is different from the proteid disintegration in the course of autolysis. The great mass of products in the process of self-digestion remains in the stage of nitrogenous acids. A small part of them lose their nitrogen and a still smaller part give rise to carbon dioxide. In the living organism the splitting off of nitrogen from proteid material is a very rapid process, and the transformation of all carbonaceous material to carbon dioxide also occurs with much

24. Jour. of Physiol., vol. xxx, 1902.

25. Ibid., vol. 31, 1901.

26. Zeitsch. f. phys. Chem., vol. xIII, 1901.

greater rapidity than it possibly could take place in course of self-digestion. But it has been stated that disintegration by the process of autolysis does occur during life. This and the foregoing are not contradictory one to another. Every tissue consists of cells of different age, of different states of nutrition and of different resistance. Work on hemolysis has brought out most clearly that individual blood cells vary in their vulnerability. Cells in a state of defective nutrition succumb to the process of self-digestion. In the course of that process enzymes are liberated which are capable of digesting extraneous material also.

It is difficult to demonstrate the correctness of this view on a complex organism, but it is made very clear from observations on the yeast cell. It is the function of that organism to convert grape sugar into alcohol. So long as conditions for this function are favorable there is little evidence of the process of self-digestion in a colony of yeast cells. But as soon as conditions are so altered as to make the normal life and the alcoholic fermentation impossible, a very active proteid-splitting enzyme is developed by the yeast cell which causes digestion of the cell proteid and of other proteid material. In the living organism the two forms of metabolism undoubtedly coexist. One is the result of the function of the organs, the other of their disintegration. The supply of energy required for the maintenance of life is furnished possibly by the first process. It has already been stated that by means of autolysis proteid is converted principally into amino-acids. By this conversion proteid could not furnish the organism with its full calorific requirement. On the other hand, autolytic enzymes may act on cell proteid and on the surrounding proteid in a manner similar to that of the enzymes of digestive glands, namely, rendering them a more suitable material for rapid combustion.

It is marvelous that, notwithstanding the presence of destructive agents in all tissues, organs succeed in guarding their integrity. A most clever investigation of recent years throws light on the mechanism by which this is accomplished. The integrity of the gastric wall, the function of which is to elaborate digestive enzymes, has been the cause of much speculation. Weinland²⁷ demonstrated that this was due to the presence of an antiferment in the digestive glands. In the blood also were found antitryptic substances by Hahn,²⁸ Landsteiner,²⁹ Glaesner³⁰ and Catchart.³¹ The same property was noted in tissue extracts by Dr. Stookey and myself.⁷ Furthermore, we have demonstrated that tissue extracts exercise an action antagonistic to that of autolytic enzymes. However, in health the two tendencies are so regulated that the tissue disintegration is sufficient to permit the organs to perform their function, while excessive wear is avoided. But as soon as the normal nutrition of the organism is disturbed the autolytic power of tissues increases. The mere fasting of an animal suffices to occasion in the tissues an exaggerated tendency for self-destruction. This was demonstrated by the experiments of Lane-Clayton and Schryver.³² It has been known for years that in cases of starvation animal organs lose in weight and that the loss varies in different organs. It is not improbable that products formed by disintegration of some organs serve to support the integrity of other more important organs.

More marked is the high destructive power of tissues in diseases of a grave nature. Thus in diseases of the respiratory system and of the heart, an intense self-digesting tendency of the tissues was noted by Schlesinger. In infectious diseases a similar observation was made by Flexner.³³ The work of this author preceded that of Schlesinger,²³ and is very important for the reason that it furnished an interpretation for some old observations of pathologists.

Flexner demonstrated an unusually high rate of self-digestion in organs removed from individuals who succumbed to typhoid fever and other infectious diseases. The observation on typhoid is of special interest, since the exaggerated autolysis in the course of the disease can not be ascribed to the action of the micro-organism, for it is known that the proteolytic power of that germ is very slight. That this high rate of self-digestion is not merely a postmortem phenomenon may be concluded from the old clinical observation, that products of proteid digestion are eliminated by the kidneys in the course of infectious diseases. The occurrence of peptonuria in these pathologic forms is not infrequent. Thus, in the light of the new investigation, this symptom acquires a special significance. So long as the nutrition is in a sufficiently good condition to prevent wasting of the tissues of the body, pepton is not present in the urine.

However, the softening and the wasting of tissues is most striking when these are under the influence of protoplasmic poisons. For this reason the study of phosphorus poisoning has attracted great attention. Martin Jacobi⁶ first pointed out the high rate of autolysis of the organs removed from animals killed by phosphorus poisoning.

In this condition self-digestion takes place not only in surviving organs, but also during life. This may be concluded from the work of Abderhalden²¹ and his co-workers, who recently have demonstrated the presence of the crystalline components of the proteid molecule in the urine of animals poisoned with phosphorus.

The importance attached to the study of phosphorus poisoning is largely due to the resemblance which the clinical symptoms of this condition bear to that of a spontaneous pathologic form known as yellow atrophy of the liver. While the morphologic changes in the liver in the two conditions are not absolutely identical, still they present many points of similarity. The most striking are the disintegration of cellular elements and the so-called fatty degeneration of the organ. Through the work of many investigators, and particularly through that of Wakeman and Waldvogel, it has become evident that the changes which the liver undergoes in these pathologic conditions are identical with those which the organ suffers in the course of autolysis. Indeed, the fact that the liver of persons who have succumbed to yellow atrophy contains products of proteid digestion was demonstrated by Salkowski more than twenty years ago and was recently corroborated by Alonzo Taylor.³³ However, in neither of the two forms are the changes limited to one organ. Jacobi has demonstrated that the blood in phosphorus poisoning presents a striking loss of coagulability. Still more striking is the power it possesses of liquefying coagulated blood. This peculiarity was interpreted as being due to the presence of a proteolytic enzyme in the blood. In the course of yellow atrophy, products of a proteid cleavage have been

found in the blood by Frerichs. This has been corroborated by many investigators, and very recently Neuberg and Richter³⁴ have shown that leucin, tyrosin and lysin may be present in the blood in quantities which clearly show their origin could not be limited to the liver alone.

Thus, in the foregoing forms all tissues are apparently affected in the same manner. Marked autolysis in them may be considered a symptom of decline in general health and nutrition. However, there are conditions in which self-digestion is located in one organ only; thus the atrophy of the thymus, the involution of a puerperal uterus, are accomplished by a process of autolysis. The softening of tumors is brought about by the same mechanism. This was made clear through the work of Petry,³⁵ who demonstrated that freshly removed tumors contain products of proteid cleavage. The same author further demonstrated that the rate of self-digestion of the new growth is higher than that of a normal tissue. An attempt was also made to study the toxicity of the products resulting from this process. However, neither from a chemical nor from a pathologic point of view could a difference between the end-products of autolysis of tumors and those of normal tissues be detected. Indeed, the intensity of self-digestion is high in all organs composed of cellular elements endowed with rapid growth.

The occurrence of local autolysis is not, as a rule, productive of a lowering in general health. On the contrary, it tends to restore normal conditions when these have been disturbed.

There are other conditions in which the process of autolysis is of aid to the organism in the efforts to maintain its integrity. It has been stated already that in the course of infectious diseases tissues possess a high power of autolysis. Investigations of Blum,³⁴ Conradi³⁵ and Levaditi³⁶ have shown that autolysis may be one of the means to which the organism resorts in order to elaborate protective substances. Substances of two distinct groups are formed in the organism as the result of infection. Those of one group aim to destroy the micro-organism and are designated bactericidal; the purpose of the other is to neutralize the toxin elaborated by the micro-organism; these are commonly named antitoxin. Normal tissues in the course of autolysis may give rise to substances of either group.

Blum has shown that the products of autolysis of lymph glands possess the power to neutralize tetanus and diphtheria toxins and cobra venom. The mechanism of this action is not based merely on the physical properties of the autolyzed gland, for it is possible to save animals from death by injecting the products of autolysis subsequent to the injection of toxin.

Further, Conradi has tested the bactericidal power of the products of self-digestion of various organs. This author noted that the last, added to a suspension of bacteria in broth, prevented their growth. The intensity of bactericidal power varied in different organs, as presented in the following table:

Muscle	Strong
Lymphatic gland	Strong
Liver	Strong
Spleen	Strong
Thymus	Marked
Suprarenal	Marked
Bone marrow	Slight
Pancreas	None
Thyroid	None

Glancing over the table, one is struck by the fact that organs rich in leucocytes are most efficient in elaborating protective substances against infection. And one is naturally led to the analysis of the rôle played by the white blood cells in the effort of the animal body to maintain its integrity. A review of all the information gained concerning the action of leucocytes on the tissues shows that this is similar to the action of the digestive, tissue enzymes. A tissue invaded by the white blood cells is subject to the action not only of the local enzymes, but of those of the blood cells as well. Digestion caused by the last, strictly speaking, can not be regarded as self-digestion. However, the two processes present so much similarity that they are classified by most writers under the same head of autolysis.

The formation of proteid-digestion products through the action of leucocytes was first noted by a Russian writer, Eichwald, in 1864. The observation has been corroborated by many scientists and clinicians. Pepton has been demonstrated in pus and in the urine in all conditions associated with abscess formation. But the work that has attracted most attention and stimulated most research is that of Friedrich Müller. This author has demonstrated that in croupous pneumonia the resolution of the exudate is accomplished by a process of autolysis. The products arising in the course of resolution are identical with those occurring in proteid digestion. The mechanism of this process has been interpreted by Flexner, who, studying the intensity of autolysis in different stages of croupous pneumonia, observed that the intensity was very high in the stage of gray hepatization and very low in the stage of red hepatization, and explains this by the abundance of leucocytes in the exudates in the first condition and their scarcity in the other. Flexner also noted that in unresolved pneumonia the autolytic power is very imperfect. In this condition, as is well known, the exudate is very poor in leucocytes.

Flexner is inclined to interpret the failure of absorption of the exudate in unresolved pneumonia as being due to the disproportion between the leucocytes and the other constituents. Indeed, the correctness of the assumption that the absorption of an exudate is accomplished by the action of leucocytes was established by the work of Opie,³⁷ who has noted that a fresh exudate does not possess the same degree of autolytic power as an old one. He has also noted that the lack of self-digestion in the first is due in some degree to the presence in the serum of a substance checking the digesting action of the blood cell. The rôle of the leucocyte in the absorption of inflammatory exudates has been previously described by Ascoli and Mareschi³⁸ and by Umber,³⁹ but the details of the mechanism were not fully understood until the appearance of the work of Opie. The discovery of the substance capable of keeping in check the destructive work of the blood cell is of great value for the understanding of the process. And it is now established that in the white cell the organism finds its most active factor for repairing the damaged and inflamed tissue.

There still remains to be discussed one point in the mechanism of leucocytic action. Regarding other tissue enzymes it has been stated that the destruction of the cell always precedes their liberation. Many writers have surmised that this applies also to the white blood cell. And yet this has not been fully established. The obser-

vation that in leukemia autolysis is noted during life seems to contradict the foregoing assumption. However, it is possible that the dead cell exercises at least a greater digestive action than the living. Hedén²⁴ and Opie have demonstrated that from the white cell two enzymes can be obtained. One resembles the enzyme elaborated by the pancreatic gland, the other the autolytic enzymes. It is conceivable that the first is secreted during the life of the cell, the last liberated only after its death. It is possible also that, once set free, the autolytic enzyme increases the power of the other enzyme. An analogous action of the spleen on the pancreas has been assumed by many writers and was proven by Stookey and myself. Thus waste and repair are controlled to a large extent by the same factors.

Autolysis, then, is the process by which dead tissue is not only prevented from becoming a burden to the organism, but, in addition, becomes converted into useful fuel material. By the aid of these processes diseased tissues, pathologic formations and new growths are removed and replaced by normal healthy tissues. The organism resorts to this process also for elaboration of protective substances against bacteria and bacterial toxins. It still remains to be demonstrated whether or not in the course of autolysis enzymes are formed which are concerned in producing that energy which makes all animal functions possible.

AN EXAMINATION OF THE STOOLS OF 100 HEALTHY INDIVIDUALS, WITH ESPECIAL REFERENCE TO THE PRESENCE OF *ENTAMOEBA COLI*.

EDWARD B. VEDDER, A.M., M.D.

First Lieutenant and Assistant Surgeon, U. S. Army.
[Now serving in Mindanao, Philippine Islands.]

WASHINGTON, D. C.

Numerous investigators have found amebas in the stools of healthy persons, but, since they have mostly made no distinction between *Entamoeba coli* and *Entamoeba dysenteriae*, their results can not be considered in this connection.

Schaudinn,¹ however, examining the stools of healthy individuals, demonstrated the presence of the *Entamoeba coli* in the stools of 50 per cent. of those examined in West Prussia, in 20 per cent. of those examined in Berlin, and in 66 per cent. of those dwelling on the shores of the Adriatic.

Craig² demonstrated the presence of *Entamoeba coli* in the stools of healthy individuals in 65 per cent. of the cases and in 50 per cent. of the 150 cases examined of patients suffering from other than intestinal disease.

These results would seem conclusively to demonstrate the fact that the *Entamoeba coli* is an extremely common intestinal parasite and the strong probability of its innocuous nature. But while Strong,³ in an investigation carried out in the Philippine Islands, a place where we should naturally expect to find this organism at least as widely distributed as it is in the United States, found only 8 out of 200 individuals infected with *Amoeba coli* (Strong), and Musgrave and Clegg⁴ state that "all

amebas are or may become pathogenic," further observations on the *Entamoeba coli* are not out of order.

METHOD.

In order to determine if it was possible to find the *Entamoeba coli* in an ordinary hard stool, a number of such specimens were examined by triturating small portions of the stool in normal salt solution with a platinum loop on the glass slide. In a number of cases this method was successful, and it is probable that the administration of salts only facilitates the finding of amebas by furnishing a ready-made liquid stool in which the amebas have become dissolved out of the hard fecal matter and become suspended in the fluid. As previous investigators have usually administered salts, however, the following method was adhered to in obtaining the 100 stools considered here: 60 c.c. saturated solution of magnesium sulphate were administered and the liquid stool examined as soon as passed.

The results obtained from this examination are classified in the following tables, but before proceeding to their consideration it should be stated that the natives examined were members of the Philippine constabulary and Philippine scouts, mostly the former, and that the white soldiers were taken partly from the Hospital Corps and partly from Companies A and D of the 20th U. S. Infantry. At the time of examination they were all stationed in the Cottabato Valley, Mindanao, P. I. The natives come from all parts of the islands, and, while a large proportion of them are Moros, they have served in other islands. The American soldiers come from 24 different states of the Union, and are, therefore, not drawn from any particular district. All of the men were in good health and on active duty at the time examined. Two of the Americans have a history of chronic dysentery several years ago. This may have been simply some form of enteritis associated with the *Entamoeba coli*. Both men are in perfect health at the present time.

The characteristics of the *Entamoeba coli* observed in these specimens as distinguished from *Entamoeba dysenteriae* are as follows:

ENTAMOEBA DYSENTERIC.	ENTAMOEBA COLI.
25-30 Microns.	10-20 Microns.
SIZE.	
(Not a distinguishing feature.)	
SHAPE.	
Usually some other shape.	Spherical when resting.
COLOR.	
Greenish.	Opaque grayish.
PROTOPLASM.	
Ectoplasm and entoplasm easily distinguished.	Ectoplasm and entoplasm distinguished with difficulty.
Ectoplasm very refractive.	Ectoplasm not refractive.
Ectoplasm finely granular.	Ectoplasm homogeneous.
Ectoplasm coarsely granular.	Ectoplasm finely granular.
PSEUDOPODIA.	
Large and easily distinguished.	Entirely ectoplasm. Hard to distinguish.
Contain ectoplasm and entoplasm.	
VACUOLES.	
Many vacuoles.	Vacuole absent usually. Never more than one.
NUCLEUS.	
Often absent. When present structure of nucleus hidden except in stained specimens. Nuclear membrane not well defined.	Almost invariable with well-defined nuclear membrane and other structure.
Changes position markedly.	In moving organism retains its relative position.
RED CORPUSCLES INGESTED.	
Many.	None observed.
MOTILITY.	
Great progressive motility.	Often absent, and when present, of limited extent and short duration.

These are a part of the differences observed by Craig² to exist between the two species. In this investigation no attempt was made to differentiate the two species by

1. "Arbeiten aus dem Kaiserlichen Gesundheitsamte," 1905, xix, No. 3, p. 563.

2. "Observations on Amebas Infecting the Human Intestine," American Medicine, vol. ix, Nos. 21, 22 and 23, 1905.

3. "Circulars on Tropical Diseases," No. 1, February, 1901, p. 10, Manila.

4. "Bulletin No. 18," Bureau of Government Laboratories, Biologic Laboratory, Manila, P. I.

stained specimens or by observation of the various methods of production, since the object desired was to demonstrate the presence of the *Entamaba coli* by a simple clinical examination such as is generally applied to suspected cases of amebic dysentery; at the same time reproduction of fission was observed in several cases, while reproduction by encystment was never seen.

It follows as a result of these observations that not only is *Entamaba coli* often present in the intestines of normal individuals in this region, but that it is by far the most common parasite, having been found in 50 per cent. of the American soldiers examined, while the next most common parasite, the *Cercomonas intestinalis* was only present in 24 per cent. of the cases. In the natives the *Entamaba coli* was present in 70 per cent. of the

ducing a certain disease and which is also present in from 50 per cent. to 70 per cent. of normal individuals.

The presence of *Ankylostomum duodenale*, which we know is of pathologic significance, in 64 per cent. of the normal natives examined, may at the first seem to contradict this statement, but a further consideration shows this to be by no means the case. The ankylostoma were, indeed, nearly as widely distributed, but were very few in number in any given case (see below), and the malevolent influence of two or three of these minute worms would be negligible. It is only when present in great numbers that they cause a sufficient loss of blood to produce the anemia characteristic of ankylostomiasis.

WHITE SOLDIERS.

cases examined, while the next most common parasite, the *Ankylostomum duodenale*, was present in only 64 per cent.

RELATION OF THE ENTAMABA COLI TO AMEBIC DYSENTERY.

These results simply tend to strengthen the position previously taken by Schaudinn,¹ Craig² and others that the *Entamaba coli* does not produce dysentery. It is true that agents which we know produce pathologic conditions may be sometimes found in healthy individuals, the resistance of these individuals being explained by their immunity or relative insusceptibility, but we know of no parasite which is accredited with the power of pro-

But perhaps the *Entamaba coli* were also present in very small numbers? This is undoubtedly true in some of the cases, especially among the Americans, but in other cases they were present in myriads. Often it was very hard to find a field which did not contain two or three, and in native Case 49, I counted 39 *Entamaba coli* in a single field, and it would have been hard to find a field which did not contain from ten to twenty. This from a single droplet of the stool. And, besides the problem is entirely different in the two cases, for the *Entamaba coli* possesses the power of indefinite multiplication in the intestines, while the ankylostomum can only be increased in any individual by reinfection.

Nor can we say that perhaps this man would develop dysentery later, for, although but a single specimen stool was examined from the majority of these cases, all the men have been under observation for a period of nine months and none of them has developed dysentery.

Several of the men have been examined at intervals of several months to see if the *Entamoeba coli* persisted in the stool for any length of time. In Case 15 of the Americans and in Cases 13, 31 and 49 of the natives amebas were always found at each examination. These cases were selected for continuous observation, for the reason that the parasite was present in abundance and easily found when search was made. In this connection it may be remarked that Craig,⁵ in refuting the view of Musgrave and Clegg that individuals presenting *Entamoeba coli* in health have never been observed for a long enough time to be positive as to whether or not dysentery might result, states that he has observed such individuals for a period of six months and has found these parasites constantly present.

CONCLUSION.

The *Entamoeba coli* can not be considered as the cause of chronic dysentery, since it is found as a continuous infection in about 50 per cent. of all normal individuals in many localities. It follows that no diagnosis of amebic dysentery should be made by the microscopist unless he has found the *Entamoeba dysenteriae* as distinguished from the *Entamoeba coli*.

The *Ankylostomum duodenale* is the most important of the intestinal worms found. This parasite seems to be very widely distributed among the natives in this locality, although I have not seen a single case of typical ankylostomiasis during a period of observation lasting ten months. This is apparently because the parasites were not present in large numbers in any individual. In the majority of the natives examined two or three ankylostoma eggs could be found in a single slide after a careful examination, but they are present in much larger numbers when the parasites are abundant enough to produce anemia.

Generally the development of the embryo in the intestine does not progress beyond segmentation of the egg, but it is worth recording that in one specimen, that of Native 14, examined immediately after its passage, numerous free swimming ciliated rhabditiform embryos were seen. This stage is not usually attained until one or two days after leaving the intestine. Ova in various stages of development, including advanced periods of segmentation, and eggs containing moving embryos on the point of hatching were also found.

A point of interest in diagnosis may here be made. No case should be diagnosed as ankylostomiasis and so treated merely because a few of the eggs of this parasite are found. To do this seems to be a tendency of most practitioners who come from a region where the ankylostomus is unknown to a locality where it is frequent. It is safe to say that no case should be diagnosed as ankylostomiasis unless presenting the characteristic symptoms of this condition, combined with a large number of eggs in the stool. In this connection I would like to quote Manson,⁶ who says: "It is not in every instance in which the ankylostomus is present that consequences so serious ensue. There may be dozens of ankylostoma in the intestine without any appreciable anemia, or, indeed, symptoms of any description what-

ever. Grave symptoms are the exception. One must be careful, therefore, to avoid concluding that the ankylostomus is the cause of every pathologic condition with which it may chance to coexist."

The other intestinal parasites may be dismissed briefly as of little or no pathologic significance. The one case of tapeworm occurred in native No. 14, who was a Filipino and not a Mohammedan, and therefore was not prevented by his religion from indulging in pork. He was entirely unaware of its presence, and had not missed a day from duty as the result of five parasites that he harbored.

This wide dissemination of intestinal parasites among the natives is, no doubt, facilitated by the universal custom of the Moros, who are Mohammedans, of defecating in the river, and the fact that, excepting the few Americans living here, it is also a universal custom to drink this river water unboiled. The number of natives infected with one or another of the parasites considered above as compared with the number of Americans infected probably furnishes some index of their relative liability to other water-born intestinal affections. Thus out of fifty natives examined there were only two in whom no parasite of any kind was found, while out of the same number of Americans twenty-one had no intestinal parasites, making the relative liability ten times as great among natives as among Americans. Or, considering the ratio of the total number of infections in the natives to the total number in the Americans, we have 428 to 45—nearly three to one. We may say, therefore, that the native soldier is between three and ten times more liable to water-born intestinal diseases than the American soldier. The native soldier in this locality uses plain river water, while the American is furnished distilled and boiled water, with occasional relapses to the unboiled water during "hikes" and in Chinese restaurants.

While, to be sure, there are other methods of disseminating intestinal diseases besides the drinking water, surely the advantages of boiled or distilled water are thus made sufficiently plain.

A CASE OF RIGHT SUBCLAVIAN ANEURISM— ATTEMPTED ENDOANEURISMORRHAPHY (MATAS).

CURE FOLLOWING SIMULTANEOUS LIGATION OF COMMON
CAROTID AND FIRST PORTION OF SUBCLAVIAN.*

HOWARD LILIENTHAL, M.D.

Attending Surgeon to Mount Sinai Hospital.

NEW YORK.

A study of the classical paper by Matas¹ describing his operation for the cure of aneurism impressed me profoundly. The operation aims at the obliteration of the sac with comparatively little disturbance of the circulation of the part. After securing preliminary hemostasis by means of the elastic bandage, the aneurism is opened in the general course of the affected vessel and all of its internal orifices are closed by suture. The sac itself is then obliterated by rows or layers of sutures. In the case of sacculated aneurisms this procedure may be carried out without interfering with the lumen of the vessel itself. In fusiform aneurisms, however, it may be necessary to obliterate the affected vessel together with the sac, although in some cases the vascular lumen may be

1. Matas: Annals of Surg., February, 1902.

re-established by suturing around a rubber tube, the ends of which have been placed in the two main openings of the sac (afferent and efferent). The tube is to be removed before the final sutures have been tied. His discussion concerning the possibilities of the method in dealing with aneurisms of the larger visceral arterial trunks not situated favorably for the employment of the elastic constrictor was very suggestive, and I determined to give the method a trial should the opportunity ever present itself.

The present paper contains the report of a case in which Matas' operation was attempted and, although it records a failure, the lack of success should not be ascribed to the method, but rather to the fact that the steps were not fully carried out. The apparently complete recovery of my patient after the employment of the older operation of proximal ligation is gratifying, but it will not deter me from making another attempt to follow out the principles of Matas if the occasion should arise.

History.—The patient was a Russian, 40 years old, and a tailor by occupation. He had served as a soldier in the infantry of his country. For the past ten years he had suffered not infrequently from what he called rheumatism. He stated emphatically that he had never been infected with gonorrhea or syphilis, and careful physical examination strengthened my belief in his truthfulness. For about a year there had been a stabbing pain in the precordial region, which had been pretty persistent but not progressive. In December, 1904, the precordial pain began to radiate to the right shoulder and down the right arm. Soon after this a localized swelling was noted in the right supraclavicular region and there was a general enlargement of the right arm and hand, especially noticeable in the fingers. The patient also complained of a prickling sensation in the right hand. He entered one of my wards at Mount Sinai Hospital, Feb. 4, 1905.

Examination.—The man's general physical condition and nutrition were good. The superficial veins over the right supraclavicular and infraclavicular regions were markedly dilated, running over the top of the shoulder. Dullness and rather high-pitched respiration were noted in the right infraclavicular region. Above the middle of the right clavicle there was a hemispherical, strongly-pulsating tumor, a little smaller than half a lawn-tennis ball. The pulsation was distinctly expansive in character and was accompanied by a marked systolic thrill. With the stethoscope a short systolic and a short diastolic murmur could be heard. The overlying skin was not discolored, nor was it adherent to the mass. The clavicle, too, seemed to be uninvolved. The right shoulder and the entire arm and hand were slightly cyanotic and were covered with numerous minute bluish vessels. The right arm and hand were swollen so that they were considerably larger than the left, but there was little, if any, pitting on pressure. The fingers of the right hand were markedly clubbed (Fig. 1). Pulsation at the right radial was somewhat delayed and was much weaker than at the left. There was no evidence of arteriosclerosis. The temporals were visible but were not abnormally tortuous.

Operation.—Four days after admission, February 8, the patient was anesthetized with chloroform and an incision was made from the outer fourth of the clavicle to the sterno-clavicular articulation and thence for four inches along the anterior border of the sternocleidomastoid muscle. The skin flap was dissected off, the insertion of the sternocleidomastoid was divided and the inner half of the clavicle was subperiosteally resected. A temporary ligature of chromicized catgut was thrown around the common carotid artery, but not tightened, and the vessel was then followed down to its origin from the innominate. By working carefully and keeping close to the vessel, no important nerve or vein was injured. Exposure of the innominate was excellent and ligation of this vessel would have been easy. A temporary ligature of chromicized gut was now thrown around the first portion of the sub-

clavian about one-half inch from its origin, and was held by a clamp at a sufficient tension to obliterate pulsation in the aneurism. Pressure over the aneurism caused easy and complete emptying, but on release of pressure there was a gradual refilling of the sac. From the rate of this reflux, which was still further diminished by tightening the carotid ligature, I believed that it might be possible to open the sac and secure the mouths of the tributary and branching vessels, so as to treat the case by Matas' method. I accordingly pierced the most prominent part of the tumor with the point of the scalpel and cut toward the shoulder for about three-quarters of an inch. To my disappointment there was a steady, non-pulsating fountain of blood, which spouted vertically for about four inches. The insertion of my finger for purposes of exploration at once checked the hemorrhage. The only opening in the sac which I could detect was a large one, which occupied a position toward the shoulder of the patient and admitted the tip of the finger. There were no coagula. The lining wall of the aneurism was everywhere smooth. There was no indication of a tributary opening toward its cardiac side. Evidence

FIG. 1.—Photograph taken four weeks after operation. Note difference in size of the two hands, the line of the cicatrix and the asymmetry due to the transplantation of the right sternocleidomastoid muscle. (This photograph was kindly made for me by Dr. *Branower of the House Staff of Mt. Sinai Hospital.)

of irregularity indicating atheromatous degeneration or calcification was wanting. The anatomy of the aneurism, thus shown to be of the sacculated variety, may be understood from the accompanying diagram (Fig. 2).

The patient's condition, which had been excellent, now gave some indication of shock, and I determined to risk nothing further, but at once sutured the vascular wound with catgut and a hemostatic needle. The first portion of the subclavian was then ligated with double No. 3 chromicized gut after the method of Ballance and Edmunds. The carotid was also permanently ligated. The divided sternomastoid muscle was attached to the remainder of the clavicle and the wound sutured with drainage. The usual dry gauze aseptic dressing was applied and the hand and arm were enveloped in cotton and bandages.

Pain following the operation was slight, but for several days there was considerable reaction of absorption and some tender-

ness over the aneurismal tumor. The temperature rose as high as 102 F., but gradually subsided and the patient's condition never gave reason for alarm. He was kept in bed for twenty-two days and then was allowed to be about in a wheeling chair. The circulation in the right upper extremity was never poor, but there was naturally some local cyanosis and the radial pulse remained absent up to the time of his discharge, March 22, 1905, when the patient was presented before the New York Surgical Society. The cyanosis had by that time almost disappeared. Pulsation in the temporal artery returned faintly thirty-eight days after the operation.

Postoperative History.—The patient was seen about three months after the operation and the cure of the aneurism seemed to be complete. The tumor had disappeared, except a small, hard mass, and there was no pulsation in the subclavian region nor in the radial. The right hand had remained larger than the left, but was apparently progressing toward the normal. On testing the circulation by pressing and releasing the fingernails it was noted that the sublingual blush returned almost, if not quite, as promptly as in the left hand. There was still slight disability of the shoulder from the resection of the clavicle, but the bone had in great part reformed.

considered extremely dangerous. Proximal and distal ligation without opening the aneurism has been practiced and at times with success,² while extirpation (method of Purmann) has been well thought of by many surgeons. These procedures, however, cut off important blood supply and we must not forget the consequent danger of gangrene of the extremity.

If it were possible to deal with these cases after the method of Matas, which would cure the disease by obliterating the aneurism without interfering with the lumen of the vessel, there would be a distinct gain. Thus far, to my knowledge, this operation has been done only when the elastic tourniquet could be employed. My failure was due to the fact that a sufficient number of tributary vessels had not been cut off. Ligation of the thyroid axis, the internal mammary and even the vertebral would not have been difficult nor directly dangerous. A temporary ligature of the axillary would also probably have been required to keep the sac empty enough to permit suture of its orifice (Fig. 2). Matas, however, calls attention to the danger of dissecting out the aneurismal sac, since its walls are nourished, not by the contained blood, but by small vessels in the surrounding structures, and necrosis of the sac is apt to follow its clean dissection. Bearing this warning in mind, I did not wish to prejudice the vitality of the sac by a dissection sufficiently free to ligate all the vessels mentioned. Having explored the interior of the aneurism, I was aware that, in addition to what had already been done, possibly a temporary ligature around the axillary alone would control the current, but by this time a considerable quantity of blood had been lost and I felt the need of some haste. Were I called to operate in a similar case, I would certainly control the axillary before incising the aneurism.

I believe that the Matas method would have proved perfectly feasible in this instance, because I am sure that neither the thyroid axis, the internal mammary nor the vertebral was connected with the sac (Fig. 2) and that, therefore, a free dissection of the aneurism with the consequent danger of necrosis would not have been necessary. The collateral circulation into the axillary must have supplied the blood which filled the aneurism after the subclavian and carotid had been tied.

Whether or not the incision and digital (rubber glove) exploration of the interior of the sac with its subsequent suture had anything to do with the prompt clotting and the speed of cure is an interesting question.

The entire subject of aneurism of the vessels higher than the axillary is too large to be treated here. The literature of aneurism of the subclavian is rather voluminous. Dr. Eben Alexander, Jr., of the house staff of Mt. Sinai Hospital, kindly secured for me notes on eighty-nine cases, most of which were operated on before 1890. Many of these aneurisms were of the traumatic variety and the operative procedures were various. The mortality rate in the entire number from all causes was 52.8 per cent. It is, in reality, probably much higher, since failures are unfortunately less likely to be reported than successes. It seems, however, from the figures of Jacobsthal,³ in an article on the operative treatment of subclavian aneurisms, that there has been a distinct lowering of the mortality rate since 1890, probably due to improvement in technic. Thus, before 1890, 55 out of 75 cases succumbed, showing a mortality of 73 per

Fig. 2.—Diagram of the aneurism.

In reviewing this case a few of the more interesting points may be discussed. First, the cause of the trouble. In the total absence of anything pointing to general arterial disease we may perhaps conclude that the most probable causal factor may have been an injury to the healthy vessel by a direct blow, possibly with one of the angles of the rifle stock during military exercise. The aneurism, however, had not the anatomic characteristics of the traumatic variety.

Secondly, we may discuss the modern methods of treating these large aneurisms when they do not occur in an extremity. To be sure, the result here was so excellent that one might be forgiven for following the precedent another time, and yet to leave a large blood clot in a vessel to be taken care of by Nature is not the best surgical practice. Not only is there apt to be serious reaction during absorption, but there is a distinct liability to infection of the clot. The method of Antylus, which consists in proximal and distal ligation with incision of the aneurism and turning out clots and with final packing of the cavity is one which has always been

2. Dr. J. A. Blake presented a beautiful case of aneurism of the subclavian treated by this method. See report of meeting of New York Surgical Society, Nov. 22, 1905.

3. H. Jacobsthal: *Deut. Zelt. f. Chir.*, vol. Ixviii, p. 239.

cent., while since 1890 only 4 out of 25 cases were fatal, or 16 per cent. This author believes in extirpation as the proper operative procedure and reports 20.8 per cent. cures; 5 in 24.

Confining this discussion to those operations in which there has been simultaneous ligation of the subclavian or innominate and the common carotid arteries proximal to the aneurism, I have been able to find the reports of 13 or, including my own, 14 cases, with 7 deaths, or 50 per cent. mortality. Sheen⁴ has reported 12 of these cases, by various operators, including one of his own, in which there was simultaneous proximal ligation of the innominate and carotid. The thirteenth is an old case by Liston.⁵ One of Sheen's fatal cases, however, was a secondary operation, ligation having been performed for hemorrhage following extirpation of a subclavian aneurism—operator, B. G. A. Moynihan. Omitting this, we have a mortality in 13 cases of 46.1 per cent. The interesting cases collected by Wyeth⁶ illustrating the results of distal ligation for aneurisms near the heart do not concern us here.

The following are my conclusions and suggestions of technic for performing the Matas operation in sacculated aneurism of the subclavian artery:

From an examination of the literature one may readily see that the greatest danger following the ligation of the large arterial trunks is that of hemorrhage, either because of erosion of the vascular walls by the ligation, or on account of infection and ulceration into the lumen of the ligated vessel. Speaking on theoretical grounds, hemorrhage is all but impossible after endoaneurismorrhaphy (Matas). By performing this operation instead of ligation or even extirpation we shall probably greatly improve the statistics. It is simple, and, although best suited to the sacculated forms, may be perfectly feasible in certain cases of the fusiform variety. In a sacculated aneurism of the right subclavian, such as the one here reported, the technic suggested is the following: The incision should be along the anterior border of the sternocleidomastoid muscle from a point about at the level of the cricoid cartilage to the interclavicular notch, thence along the clavicle to its outer fourth. The sternocleidomastoid may then be divided at its insertion and the common carotid artery exposed and followed to its origin in order to find the subclavian. One should remember that anomalies are sometimes found here. Temporary ligatures should now be placed on the carotid and subclavian and the aneurism carefully observed, both as to pulsation and as to the refilling of the sac after it has been emptied by manipulation. If pulsation persists, or if there is a rapid refilling, a temporary ligation of the axillary is necessary. There should be no free dissection of the sac and no exposure of the smaller subclavian branches, such as the vertebral, thyroid axis, internal mammary or superior intercostal. The aneurism may now be opened by an incision small enough to be plugged by the exploring finger and the interior of the sac carefully examined to ascertain the number of large openings.

The character of the hemorrhage must be noted. It will probably not be severe and may be found to proceed from a single orifice of moderate size. There will probably not be pulsation. Endoaneurismorrhaphy may now be performed as described by Matas,¹ and on

its completion the ligatures may be removed, first that of the carotid, second the axillary, and third the subclavian. If everything is in order the wound may be closed without drainage.

In dealing with aneurism of the left subclavian the steps must be changed somewhat to suit the anatomy.

NOTE.—Soon after this paper was sent to THE JOURNAL for publication, at a meeting of the Southern Surgical and Gynecological Association, reported in THE JOURNAL A. M. A., Jan. 6, 1906, page 66, Dr. F. W. Parham, New Orleans, stated that he had cured a case of left subclavian aneurism by suture of one orifice within the sac after the failure of proximal ligation.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XIII.

ASTRINGENTS—Continued.

METALLIC ASTRINGENTS.

The insoluble salts of bismuth are admirably adapted for the protection of the intestinal mucosa from irritations of various kinds. While as much as thirty times the average single dose of bismuth salts has been given in the course of a day, by mouth, without any distinct evidence of untoward results, absorption and poisoning have followed the external use of bismuth salts as a dusting powder when used over a large surface.

Owing to the extremely poisonous nature of bismuth when absorbed, the soluble salts seem to us to be entirely superfluous, particularly as their solubility precludes the very object for which bismuth compounds are chiefly used—that is, for the mechanical coating of the surface with a protective layer of insoluble powder. It must be admitted, of course, that even the soluble salts of bismuth are astringent, but we have many safer astringents which are harmless (that might well be used in their stead).

The activity of the nostrum-makers has resulted in placing on the market a number of preparations that are intended to combine the antiseptic properties of the benzene derivatives with the astringent properties of bismuth, but until we know more of the possibilities and the limitations of internal antiseptics it is preferable to use the simple astringents and to use our antiseptics separately.

Bismuth subnitrate, or subcarbonate, when triturated with water, should form a creamy mixture, and the physician should not permit the use of that which readily separates as a heavy powder, leaving a nearly clear stratum of liquid above it. The covering power of bismuth is in direct proportion to the creaminess of the mixture.¹

BISMUTH SUBNITRAT.—U. S.—An insoluble white powder, without odor or taste.

BISMUTH SUBCARBONAT.—U. S.—Closely resembles the subnitrate.

Average dose (of either salt): 0.5 gm. (8 grains).

BISMUTH SUBSALICYLAT.—U. S.—This preparation closely resembles the subnitrate in physical properties and is intended to combine the antiseptic properties of the salicylic acid with the astringency of bi-muth salts.

1. A typical prescription for gastric irritation, or ulcer is as follows:

R. Bismuthi subnitrat	grs. ʒi	10
Mucilaginis acacia	ʒv	50
Aque cinamomii q. s.	ʒi	100

M. Sig.: Shake well and take one or two teaspoonfuls three or four times a day.

In cases in which marked irritability persists, the addition of 0.01 gm. (1/6 grain) of cocain hydrochlorid to each dose, as a local anesthetic, may be advantageous, but we do not advise it as a routine procedure. For diarrhea one or two drops of the deodorized tincture of opium may be included for each dose, or, if preferred, 1 c.c. (15 minims) of paregoric, the official camphorated tincture of opium. For this purpose, it is usually preferable to give one dose every hour for three or four doses then every two to four hours as needed. Bismuth subcarbonate may be used instead of the subnitrate and tincture of kino, tincture of Krameria or the compound tincture of gambir (catechu) may be added in the treatment of diarrhea.

4. Wm. Sheen: *Annals of Surg.*, July, 1905, p. 1; also November, 1905, p. 802.

5. Quoted by Wyeth in "Essays in Surgical Anatomy and Surgery." Wm. Wood, 1879.

6. Wyeth, J. A.: "Text-Book on Surgery," Appleton, 1888.

Average dose: 0.25 gm. (4 grains).

BISMITI SUBGALLA.—U. S.—This substance was at one time widely advertised and is even now occasionally prescribed by its proprietary name, dermatol. It occurs as a bright yellow, insoluble, odorless and tasteless powder, which is mostly used externally as a substitute for iodoform.

Average dose: 0.25 gm. (4 grains).

Official Lead Salts.

Lead is of interest chiefly because of the chronic lead poisoning so often encountered.

The principal internal use of lead is in the form of the pill of the acetate, usually combined with opium, in the treatment of diarrhea. It has also been recommended for dysentery, but it is not nearly so useful in that disease. This preparation should not be given for any considerable length of time, lest it give rise to chronic lead poisoning. The solution of lead subacetate is unfit for internal administration, but is of value in painful swellings and local inflammations and burns. The well-known mixture of laudanum and lead water has long been popular as an external application, but any mucilaginous liquid could probably be used in place of the tincture of opium without detriment, since the astringency of the lead is the main factor, the local application of the opium alkaloids being entirely superfluous because they are not absorbed from the unbroken skin. The local use of lead water itself is so thoroughly well established that it scarcely requires further comment.²

PLUMBI ACETATIS.—U. S.—Acetate of lead, or sugar of lead, is said to have been known to Geber. It was described by Raymond Lully in the thirteenth century, but was not used in medicine until introduced by Goulard a little more than a century ago. It occurs in crystals or as a heavy white powder, having an acetic odor and a sweetish, astringent, afterward metallic taste.

Average dose: 0.05 gm. (1 grain).

LIQUR PLUMBI SUBACETATIS.—U. S.—An aqueous solution containing not less than 25 per cent of lead subacetate.

LIQUR PLUMBI SUBACETATIS DILUTUS.—U. S.—This contains about 1 per cent. of lead subacetate and is made by mixing 4 parts of the solution of lead subacetate with 96 parts of distilled water.

The Local Treatment of Mucous Membranes.

The local treatment of inflammation of the mucous membranes in the mouth, nose, throat, vagina and urethra, after thorough cleansing, preferably with a solution of hydrogen dioxide, may require mild astringents of either organic or inorganic substances, though, as previously stated, the use of the solution of hydrogen dioxide has greatly lessened this necessity. Alum has long enjoyed a particular reputation in the treatment of stomatitis, and has also been used as a gargle, but it is injurious to the teeth, and the necessary solution, made of 1 part of alum in 20 parts of water, is preferably applied directly to the affected parts by means of a camel's-hair pencil or a swab made of absorbent cotton. After gargling, the mouth should be rinsed with water. Alum is not given internally so often as it was formerly, it is irritating and possesses no advantages over other astringents. Because of this irritant action it is emetic, and, while not very dependable, may serve in an emergency if no surer emetic is at hand. Small ulcerations of the throat, after having been cleansed with an antiseptic solution, may be touched with a mixture of 1 part of ferric subsulphate and 2 parts of glycerin with a camel's-hair pencil.

A very large number of astringent gargles are in common use, but the following is a good representative of the class:

3. The following mixture will probably answer the purposes for which laudanum and lead water are commonly used:
R. Lq. plumbi subacet. gr. lxxv 5
Mucil. acac. gr. xlv 3
Aqua, q. s. ad. ℥ss 100

The solution of lead subacetate is diluted with 55 c.c. (14 drams) of water and the mucilage with 27 c.c. (8 drams) the two are then mixed. Fifteen c.c. (4 drams) of alcohol may be added to the water, but the amount of alcohol present in the mixture of laudanum and lead water is too small to be of any benefit.

R. Tincture ferri chloridi.	℥ss 10
Potassii chloratis	℥ss 12
Aque q. s.	℥vi 200

Those who object to the use of ferric chlorid may find the following preferable:

R. Glyceriti acidi tannici.	3v 20
Aque q. s.	℥vi 200

ALUMEN.—U. S.—Alum should contain not less than 99.5 per cent. of pure aluminum and potassium sulphate. It occurs as colorless crystals or as a white powder; it is odorless, but has a sweetish and strongly astringent taste. Alum is soluble in 9 parts of water, but is insoluble in alcohol.

Average dose: 0.5 gm. (8 grains).

ALUMEN EXSICCATUM.—U. S.—Popularly known as dried alum, must contain not less than 99 per cent. of anhydrous aluminum and potassium sulphate. It is used for the same purposes as alum, and in addition is somewhat caustic when dusted, as a dry powder, on exuberant growths.

The Use of Zinc Salts.

Zinc sulphate and zinc phenolsulphonate may be considered together: they have a variety of applications, and it is only necessary to suggest the strength of the solutions that are to be used for various purposes.

For the eye they are generally used in the strength of from one-fourth to one-half of 1 per cent. in a solution of boric acid, to which camphor water may be added.

For the urethra strong solutions should not be used, one-half of 1 per cent. in water being sufficient. The popular combination of zinc sulphate and lead acetate, resulting in the insoluble lead sulphate and the very astringent zinc acetate, may possess some advantages over the more simple solution, but they are not very apparent.

Vaginal douches may be somewhat stronger and are frequently prescribed of from 1 to 2 per cent. strength.

As noted before, all the astringents may act as emetics if they are sufficiently irritant to the mucous membrane of the stomach and are not caustic. Zinc sulphate, however, deserves the preference among the astringents used as emetics. For this purpose it is usually given in doses of 1 or 2 gm. (15 to 30 grains) dissolved in a teacup of warm water.

The official salts of zinc that are of interest as astringents are:

ZINCI SULPHAS.—U. S.—Colorless crystals, without odor, having an astringent metallic taste. Zinc sulphate is soluble in less than 1 part of water, but is insoluble in alcohol.

Average dose: Emetic, 1 gm. (15 grains).

ZINCI PHENOLSULPHONATE.—U. S.—The zinc sulphocarbonate of previous editions of the Pharmacopeia has been referred to under antiseptics.

Average dose: 0.12 gm. (2 grains).

ZINCI ACETAS.—U. S.—This constitutes a widely used and deservedly popular astringent.

Average dose: 0.12 gm. (2 grains).

ZINCI OXIDUM.—U. S.—A white or yellowish-white powder, insoluble in either water or alcohol, it is largely used as a local application in dusting powders and in ointments, but is seldom given internally.

Average dose: 0.25 gm. (4 grains).

Copper and Iron Salts.

CUPRI SULPHAS.—U. S.—Blue stone or blue vitriol was known to the Greeks as Chalkanthos. Discordes described it as being a valuable astringent and, in large doses, emetic. It occurs as deep blue crystals that are devoid of odor, but have a nauseous, metallic taste. It is soluble in about 3 parts of water.

Average dose as an astringent: 0.01 gm. (10 mg. or 1/5 grain); as an emetic, 0.25 gm. (4 grains).

Of the numerous preparations of iron that have astringent properties we will mention but one, the chlorid, as representative of the whole class. This is official in several forms:

FERRI CHLORIDUM.—U. S.—This occurs in orange-yellow crystalline pieces, nearly odorless, but having a strongly styptic taste.

Average dose: 0.05 gm. (1 grain).

LIQUOR FERRI CHLORIDI.—U. S.—An aqueous solution of ferric chlorid, containing about 29 per cent of the anhydrous salt.

Average dose: 0.1 c.c. (1½ minims).

This preparation is but little used, except for preparing

TINCTURA FERRI CHLORIDI.—U. S.—This is made by adding 35 parts of solution of ferric chlorid to enough alcohol to make 100 c.c. The official tincture is directed to be prepared at least three months before being used.

Average dose: 0.5 c.c. (8 minims).

This preparation is injurious to the teeth; therefore it should be directed to be taken through a tube and the mouth rinsed with water or a very mild solution of an alkali, like limewater.

Use of Silver Nitrate.

Silver nitrate in the form of the sticks, lunar caustic, is mainly used as a caustic for touching warts of various kinds and for non-granulating wounds. A solution of silver nitrate is sometimes used as an application to the conjunctiva, followed at once by a solution of sodium chlorid, whereby a momentary action of the silver nitrate is obtained, the nitrate being instantly converted into the chlorid when the solution of sodium chlorid is applied.

Silver in combination with different proteids has been introduced under a variety of trade-marked or proprietary names and recommended as a non-irritant antiseptic, mainly for the treatment of gonorrhoea. Crédé some years ago introduced a soluble form of metallic silver, for which certain manufacturers make the fabulous claim that it is an efficient disinfectant of blood and tissue. So long as septic diseases resist all treatment, it seems strange that reputable manufacturers will make such obvious misstatements.

The only official preparation of silver that is of direct interest in connection with astringents is

ARGENTI NITRAS.—U. S.—This salt is supposed to have been known to Geber, but was introduced into medicine by Angelus Sala during the seventeenth century. It is very soluble in water and occurs as colorless, transparent, tabular crystals, that darken on exposure to light in the presence of organic matter. It is odorless, but has a bitter, caustic and strongly metallic taste.

Average dose: 0.01 gm. (10 mg., 1½ grain).

The internal use of silver nitrate as an astringent is necessarily empirical, as the actual composition that is formed when silver nitrate is brought in contact with organic matter must be complex and problematic. A favorite pill of the late Dr. William Pepper for chronic gastritis was the following. It is given without comment:

R. Argenti nitratis	1
Extracti hyoscyami	1
Mannæ, aa	gr. 1 3
	102

To make one pill.

This was directed to be given three or four times a day, and the composition was occasionally varied by substituting powdered opium for the extract of hyoscyamus.

Vasoconstrictors.

In addition to the astringent drugs depending on tannin or the metallic salts, certain alkaloids possess a markedly astringent, or, more properly, vasoconstrictor effect when applied to mucous membranes. Of these, the most useful are hydrastinin, a derivative of hydrastin, from which it is obtained by oxidation, and the alkaloid of the suprarenal gland. Here we are compelled to admit that this latter alkaloid, which is now being marketed at the modest price of some \$800 per ounce, despite Abel's simple and inexpensive method of preparation, is superior to the official desiccated suprarenal gland. The application of a 1 to 1,000 solution of hydrastinin or a 1 to 5,000 solution of the suprarenal alkaloid, in 0.9 per cent. solution of sodium chlorid, to an inflamed conjunctiva or inflamed nasal mucous membrane often affords prompt relief. In view of the very great difference in cost without a corresponding difference in effect, the physician can well afford to use hydrastinin in preference to the more expensive alkaloid in such conditions.

The desiccated suprarenal gland may be macerated in water and the fluid filtered and used, but any of the preparations of

the alkaloid which appear under a variety of trade names will usually be preferred. Slight hemorrhages are also stopped by either of these means.

When the flow of blood is copious and hot water is ineffective, styptics are useful; they are not alone astringent, but also cause a sudden coagulation of the blood, and this plugs up the orifice. Large clots must be removed, as they prevent the immediate action of the astringent or styptic and may conceal a hemorrhage occurring in cavities, the uterus, for instance, in which case the clot may fill the upper part of the vagina.

It is necessary to bear in mind the difference between the action of vasoconstrictors, like the alkaloid of the suprarenal gland, and the action of styptics, like tannin or the ferric salts. With the former the action is transitory and the hemorrhage may recur as soon as the action of the drug has worn away, while styptics, when effective, form a plug in the normally extended blood vessel.

GLANDULE SUPRARENALES SICCÆ.—U. S.—Desiccated suprarenal glands are directed to be obtained from the sheep or ox, freed from fat, cleaned, dried and powdered. One part of desiccated suprarenal gland represents approximately 6 parts of fresh glands free from fat.

Average dose: 0.25 gm. (4 grains).

The alkaloid contained in the suprarenal glands has been variously designated as epinephrin by Abel, supranerin by Fürth and adrenalin by Takamine. The trade names that are now applied to the solutions of the same substance are legion, and it seems very unfortunate indeed that the committee on revision of the Pharmacopœia did not recognize the alkaloidal substance in an official way and give it an official title. The only effect to be expected from the internal administration of the gland or its alkaloid is the local constriction that is noticed when it is applied to the mucous membrane. The solution of the alkaloid is useful only for intramuscular or intravenous injection. When injected just beneath the skin it produces practically no effect, except a local vasoconstriction.

(To be continued.)

Clinical Notes

A CASE OF PRIMARY ARTERIAL THROMBOSIS OF THE EXTERNAL ILIAC ARTERY. WITH SECONDARY EMBOLI.*

M. THORNER, M.D.
INDIANAPOLIS.

Primary or autochthonous arterial thrombosis of the large vessels, other than the aorta with sequelæ, affords a sufficient incentive to a most careful analysis of each case from a clinic as well as from a histologic standpoint, as the gravity of the subsequent conditions is of paramount importance.

The occurrence of secondary emboli from thrombosis in arteries other than the aorta and pulmonary arteries gives the following case an especial significance. To Virchow is given the credit of first actually proving anatomically and clinically, as well as of having first recognized that not all intravascular and antemortem clots are formed at the place where they are found, but are the result of emboli. It is a well-known fact that embolus with secondary thrombosis plays a greater rôle in arterial occlusion than primary thrombi, yet the close relation of the latter to the former, as in this case, accentuates the necessity of such careful analysis in order to establish the dependence of the one on the other.

The pathologic findings in the following case place it in the category of primary arterial thromboses, and I

* Read before the Marion County Medical Society, Indianapolis, Ind.

have given *seriatim* the phases of the case from the point of clinical interest, and have endeavored to analyze them with reference to their influence in the production of the thrombus.

Patient.—Mrs. X., a patient of Dr. H. O. Pantzer,¹ was first seen March 10, 1905. She was a rather small woman, anemic (skin of a greenish hue), poorly nourished, 47 years old, though much older in appearance, and showed the lines of much suffering and wasting. Her only complaint now is that of repeated attacks during many years of colicky pains in the gall-bladder region, and lately she becomes jaundiced during the attacks.

Physical Examination.—The heart was not enlarged; its action was regular and sounds were normal. The radial artery was soft and easily compressible; temporals could be seen, but were faintly outlined and soft. The lungs were negative. In the abdomen, in the region of the gall bladder, a pear-shaped tender mass projected below the free border of the ribs. The liver dimensions otherwise were normal.

Operation and Result.—April 1, under chloroform, cholecystotomy was done, and many gallstones were removed. Convalescence was uneventful until April 9, when the patient had an attack of severe abdominal cramps in the epigastric and hypogastric regions and to the left of median line, accompanied by repeated vomiting. An enema was given, and this was followed by a discharge of a large amount of disintegrated blood and some fecal matter. Nothing was found in vagina or rectum to account for the bloody discharge. Twelve hours later there was a similar discharge of gases, fecal matter and blood. Pain gradually localized itself in the abdomen just below and to the left of umbilicus, where an indefinite tumefaction could be made out, with marked tenderness over same. Castor oil was given and free evacuation of bowels followed; the stools were normal. Pulse was 120; temperature, 101.4.

Further Course of Disease.—There was general and local improvement. Pulse and temperature were nearly normal. Early in the morning the patient complained of sharp pain and numbness in the left ankle and foot extending to knee, but after a few hours this entirely disappeared, and nothing unusual was observed in the foot. Twenty-four hours later the patient experienced a sudden, excruciating pain in the left foot extending to the knee. When seen six hours later the foot was pale, cold, and extremely tender to slightest touch. The veins were apparently empty in this extremity; there was no pulsation in the anterior tibial artery and but very slight pulsation in the left popliteal. The left femoral pulsated, but the tension was much less than in the right. By evening, areas of purple appeared over the distribution of dorsalis pedis artery. Physical examination of the heart revealed normal sounds, no displacement; there was no enlargement and the action was regular and forcible.

April 22: The patient's general condition was retrograding, and in her poor state amputation of the limb promised little. She was removed by her relatives to her home out of the city.

May 3: The patient was visited in her home. Her general condition was better than when seen last. The tongue was dry and coated; the skin and sclera were yellowish. Temperature ranged between 99 and 102 in morning and went to 103 in afternoon. Since arriving home the affected limb has been immersed in moist and dry hot applications. The gangrene had continued to spread, and the entire foot and leg were dry and black. An indefinite mass could still be made out on deep palpation of the left side of the abdomen; it was slightly tender. No bruit could be heard over this on auscultation. Bile still discharged from the new fistulous wound. No pulsation could be felt in the popliteal or femoral arteries. Over the latter's course a hard, thick cord could be made out.

Amputation and Result.—It was decided to amputate the limb, and this I did, with the kind assistance of Dr. Pantzer and the physician in daily attendance. Amputation was done at the beginning of the middle third. On cutting through the femoral vessels, a mixed thrombus was found to occupy the

artery and a red thrombus the vein. There was some bleeding from the arteries in the anterior part of the limb, but active spurting from those in the posterior part on removal of the constrictor. The deeper circulation was evidently maintained by the crucial anastomosis. The skin circulation was not so good anteriorly as posteriorly. There was bleeding from the nutrient artery of the femur. The flaps were united, drainage inserted to inner angle, and wound dressed. The patient recovered without shock.

May 26: Margins of stump after the first week began to show malnutrition, and shortly thereafter necrosis of the flaps occurred, with separation of the same. The general condition gradually retrogressed. Temperature ranged between 99 and 101, and pulse from 90 to 130. A marked marasmic state supervened, and the patient died.

Autopsy.—After much persuasion, an incomplete autopsy was granted by the relatives, the result of which follows:

The brachial artery in the left arm had been injected with a formalin solution. There was pronounced rigor mortis. The stump of the amputated limb was powdered with some drying material. The flaps showed marginal necrosis; the bone stump was dry. A small amount of clear fluid was in the pericardium. The heart was of normal size, the valves were glistening and white, and there was no evidence of endocarditis. The ventricles and right auricle contained a small amount of blood; no thrombi or ulcerations were found on the valves or on any part of the endocardium. The first part of the aorta was examined; the valves of this, as well as of the pulmonary artery, and the vessel walls showed no changes.

Abdomen: There was a very slight amount of clear fluid in the peritoneal cavity. The omentum was found intimately adherent to the anterior and lateral abdominal walls in the left iliac region and to a coil of small intestines, which it almost completely hooded in. This coil of small intestines, about eight inches in length, was situated below and to the left of the umbilicus. It was acutely kinked on itself, much distended, the contiguous margins of the kink closely adherent, and the whole coil adherent by not marked adhesions to the lateral and posterior abdominal walls. At points near the beginning of the upper limb of the kink and near the end of the lower limb were two apposed necrotic areas, the size of a 10-cent piece, and opposite the mesenteric attachment, which had involved nearly the whole thickness of the intestinal walls. Coincidentally, this entire mass was directly over the left common iliac artery.

Stomach: This viscus was contracted and small, and presented no evidence of inflammatory thickening or tumor.

Liver: This organ was small, anemic, and on section apparently the seat of fatty changes.

Spleen and Pancreas: This was somewhat enlarged and hard, and the pulp was deeply congested.

The pancreas was not enlarged, but was anemic. On section nothing abnormal was noted. The splenic vein was not thrombosed, and the retroperitoneal glands not enlarged.

Left Kidney: The capsule was somewhat thickened and in places adherent. On section the tissue was pale; the striæ were well shown.

Arteries: The left common iliac artery contained a thrombus up to about three-quarters of an inch above its bifurcation into the internal and external iliacs. The left common iliac and external iliac were dissected out and removed for examination to a point about an inch above Poupart's ligament. The femoral artery and vein were also dissected out and removed to one inch below Poupart's ligament. The popliteal artery and vein were dissected out and removed from the amputated limb, which until now had been kept in a strong formalin solution. The dorsalis pedis artery, with the tissue around, was in part excised, its lumen was not obstructed and contained but a thin clot.

Histopathology.—The kidney showed marked parenchymatous degeneration, affecting chiefly the convoluted tubules. The glomeruli, for the most part, were considerably contracted; there was congestion of the cortical blood vessels, but no interstitial deposits. The whole aspect was that of a parenchymatous degeneration of considerable degree. The arteries of the kidney show no arteriosclerosis whatever. The

¹ This case occurred in the service of Dr. H. O. Pantzer, of Indianapolis, to whom I am indebted for the privilege of reporting it.

liver showed moderate fatty degeneration, without special reference either to the central or peripheral parts of the lobule. The pancreas was negative.

Section of arteries: Commencing about one-half of an inch from the upper end of the common iliac section (really the lower half-inch of the artery), the intima was very much thickened (due to proliferation of the subendothelial layer) and projected into the lumen for about 1.5 the diameter of the vessel. This was a node in form, as a very short distance below and above this the intima was but slightly thickened. The media showed a granular degeneration opposite the intimal thickening and was thinned out here. The adventitia showed no thickening or infiltration. The vasa vasorum showed no changes. The contained thrombus was, for the most part, of the mixed type, varying with red. Examining the thrombus from above downward, the first evidence of organization was seen at the beginning of the external iliac artery. This organization sprang from the intima on the same side as the intimal node above, and consisted of a stroma of fairly old connective tissue, and projected into the lumen of the vessel for about one-third its diameter. This was the only point in all the sections of the arteries where there was organization, and this was most probably the oldest part of the thrombus. The intima in the different sections was very slightly thickened throughout. The media nowhere else, except in the part mentioned, showed any degenerative changes or round-celled infiltration. The vasa vasorum showed no obliterative endarteritis in any part of the sections. The internal iliac (a small section examined), besides containing a mixed thrombus, showed no structural changes. The popliteal and femoral veins, in the sections examined, contained a red thrombus for the most part; some of the sections, however, showed mixed thrombi. That part of the femoral vein just below Poupart's ligament showed beginning organization; this was the only point in the veins where organization was found. Bacterial staining was made only of the thrombus contained in the popliteal artery, but no bacteria were found. This was the only part of the thrombus examined for bacteria, first to establish the presence or absence of a bacterial embolus, and, second, to determine if that part of the thrombosed vessel above the amputation, exposed to contamination as it was, would offer no proof as to whether or not the primary thrombus contained bacteria.

Remarks.—The study of the physical signs and the histopathology in this case—the soft radials and temporals, and the absence of degenerative or other changes in the walls of the other large vessels examined—would point to the primary changes found in the common iliac as a local process.

DISCUSSION OF THIS CONDITION.

In determining the etiologic factors in the production of this localized arteriosclerosis, there were conditions which do not harmonize with the usual course in the arteries after syphilis or senility—there were no caseation or calcification, no cellular infiltration, nor were the vasa vasorum opposite the intimal thickening (or at any other point) in any but a normal condition. The change seemed to have been primarily in the media, in the form of a granular degeneration; the media was thinned out at this point and compensatory hypertrophy of the intima followed. There was entire absence of specific history or symptoms of alcohol or gouty manifestations, yet, in the presence of a parenchymatous degeneration in the kidney and fatty changes in the liver, there must have been some other toxic influence present, probably from the gangrenous intestine, and the intestinal disturbance following.

It is evident, also, from the microscopic findings in the artery, that the thrombus formation began not at the point of greatest intimal thickening, but at a point about half an inch below. This being the oldest part of the thrombus, it was from here, most probably, that the embolus was cast off, and from this a secondary ascend-

ing thrombus resulted. From the sequence of events the embolus most probably lodged in the anterior tibial artery.

The compression of the common iliac by the mass of intestines bound down above it lent its influence in affecting the blood current at this point, and the formation of slight eddies beyond the projection of the intima would seem a most natural site for thrombus formation, and at this point, indeed, was found the oldest part of the thrombus.

We have here, therefore, the cardinal factors in thrombus formation, namely: disturbance in circulation; local lesion in the vessel wall; changes in the chemistry of the blood—a marasmic state which may have been primary or secondary to the toxemia from the intestines.

The diagnosis of the embolus in this instance was typical of such a state. The first embolic impact, though marked, was not intense. Then followed a subsidence of the symptoms after a few hours, and twenty-four hours later there followed what I believe to have been a second embolus, when the symptoms were sudden and very intense.

The occurrence of a "reflex chill" at the time of embolic impact was absent in this case. Dr. W. H. Welch states that chills associated in such cases are due usually to infection rather than to vascular plugging.

The temperature about the time of the embolism was $99\frac{1}{2}$, rising to $100\frac{1}{2}$ (rectum) in the evening. The patient had a slight elevation of temperature before this attack, and the amount of temperature due to the embolism or thrombosis can not be stated. Dr. Welch states that, independently of the intervention of pathogenic micro-organisms, arterial embolism may be accompanied by temperature. Gangolphe and Courmont attribute the fever sometimes observed after arterial occlusion to the absorption of pyrogenetic substances which they find in tissues undergoing necrobiosis.

The prognosis in cases such as this one must necessarily be grave. I can not see how any assistance can be rendered in saving the limb or even the life in a case like the one I report, unless cicatrization and healing first take place in the original site of the thrombus, from which point secondary emboli may continually be displaced, and from which, in turn, other thrombi are formed, even if the primary thrombus itself does not become an occluding thrombus.

TREATMENT.

From the pathologic findings in this case it would seem that, barring the infectious emboli, conservatism, namely, awaiting definite developments in the part, is the safest manner of handling such cases. At first palliative measures should be used for the encouragement of collateral circulation, provided, of course, that from the anatomic conditions this can be accomplished, and if the process is not rapid. Routine treatment in general consists of elevating slightly the affected limb and enveloping it in warm compresses or solutions. In the palliative treatment I would suggest, further, that the affected limb should be treated most aseptically. The limb should be shaved and the part thoroughly cleansed and kept continuously under the influence of mild antiseptics, preferably dry, so that in case of local gangrene the danger of sepsis is largely avoided and more time allowed for the recovery of the part or for a line of demarcation to form. Beginning with the onset of the embolism or other evidence of thrombosis it would seem

that the iodine preparations should be given to aid in the absorption of the new-formed tissue, as well as to treat a possible specific basis for the arteriosclerosis. If the resulting gangrene is so extensive that amputation is necessary, this, of course, must be done, but well up in healthy tissue, where this is possible.

224 North Meridian Street.

RETENTION OF URINE CAUSED BY ENLARGED PROSTATE AND RELIEVED BY PROSTATECTOMY.*

GEORGE W. KING, M.D.

HELENA, MONT.

Patient's History.—Twelve years ago the patient had an attack of retention while out prospecting and had to travel a distance of fifty miles to reach medical aid. He was easily relieved by the use of a catheter and instructed in the care and use of the instrument. By its aid he was enabled to go on with comparative comfort until a recent date.

For many years he has resided alone in a cabin situated near an infrequently traveled road, and when the present attack of retention came on there was no available way of securing assistance. He had been a sailor at one period of his career and having a flag in his possession he naturally conceived the idea of floating it at half mast as a distress signal. After some days, fortunately, it attracted the attention of a passerby who went into the cabin, and, discovering his condition, took him to the nearest physician where an attempt to pass a catheter was made without success.

View of the prostate removed; weight, 5½ ounces.

Hospital History.—He was immediately sent to the hospital and came under my care. He had a history of five days' retention and there were already symptoms of uremia. Obviously the first thing to do was to relieve the retention by the usual method if possible. The prostatic obstruction was found to be so great that no form of soft catheter could be passed. A metallic instrument with long curve was made to enter the bladder without serious difficulty and a considerable quantity of bloody urine evacuated. The amount taken away did not exceed one-third of the contents of the bladder. This was amply sufficient to afford temporary relief, which was the most urgent indication at that time. By this plan too sudden reduction

of pressure on the bladder, ureters and kidneys was avoided and time was gained for further investigation. The introduction of the instrument caused so much pain it was used but twice in the twenty-four hours instead of at shorter intervals. This treatment was continued during the three days preceding the operation. The obstruction being seated so high up in the pelvis, it was a debatable question which route to choose. The perineal was finally decided to be the safer in this instance and was therefore given the preference.

Operation.—The operation was begun with the expectation that it would be difficult and so it proved to be. The growth could not be brought down by the sound or by any of the tractors designed for the purpose; hence the work had to be done almost entirely by the fingers, guided by the sense of touch, to define the boundaries of the diseased tissue. By patience and perseverance the mass, as seen in the accompanying illustration, was removed and free drainage established. The patient withstood the operation remarkably well for one of his years; there was no shock, and no elevation of temperature after the reactionary stage had passed. He was allowed to get up when he pleased. In fact, he did get out of bed on the day following the operation, but of course did not move about much for a day or two.

His convalescence has been exceptionally rapid, a small amount of urine came through the natural passage on the sixth day, which is not the rule. With a complete healing of the wound I believe his troubles will be over.

ICE-BAGS AND WHEN TO USE THEM.

P. A. AURNES, M.D.

MINNEAPOLIS, MINN.

The reluctance with which the laity used to submit to the application of ice-bags or to the use of cold water in disease is fast disappearing. Wholesome and general awakening to the full appreciation of the great remedial power possessed in the scientific application of simple means like water and its different forms, vapor or ice (hydrotherapy, thermotherapy or frigerotherapy) instead of relying on antipyretic and analgesic drugs, when fighting systemic or localized inflammations, is evidence that the teaching of men like Esmarch, Winternitz, Schlikoff and others is gaining ground.

There is, however, still field for educational work, not alone among the laity, but also among physicians, as there are many who still keep on "crossing the river in going after water," as the saying is.

Many medical men know the value of cold applications as well as the danger of antipyretic and analgesic drugs, yet they lack the moral courage to carry theory into practice from fear of being discharged by an ignorant patient for applying anything so "dangerously" cold as an ice-bag. Furthermore, some men relegate themselves to the rear guard of the profession by condemning at all times the use of hydro-therapeutic measures and cold applications in any form, and prefer to stick to the dirty, antiquated flaxseed poultice or to some proprietary "mud" preparation with its cure-all qualities.

Scientifically considered, heat and cold differ only in degrees, but let it be understood that, although the physiologic effect during their application within certain limits may be identical, there is a distinct difference in the results obtained, when they are applied to parts, where a pathologic process is in evidence.

Thus a warm poultice application tends to relieve pain, but it also tends to favor the formation of bacterial growth—the formation of pus—when pyogenic germs happen to be the cause of the inflammation. On the other hand, if an ice-bag be applied to such a region it will not alone relieve congestion and pain, and that

*Presented at a meeting of the Lewis and Clark County Medical Society.

more effectually than any bearable hot application ever can do, but, what is usually of greater importance, it tends to prevent the formation of pus, it will cool the region involved to such an extent, even if the trouble be deep-seated, as proven by Winternitz, Esmarch and others, that the growth of bacteria is retarded, if not entirely checked.

This relation of bacterial invasion and growth to the majority of acute inflammations is an established fact, and it is further true that such growth is retarded or entirely checked, and that the cardinal symptoms of inflammation, redness, heat, pain and swelling are effectually relieved and even the fever of a systemic infection materially reduced by the proper application of ice-bags. It is the opposite of good treatment to apply warm applications to acutely-inflamed regions, especially when pus-producing germs are suspected to be at work, unless the purpose be to aid in the production of pus, which seldom is the case and never should be, if treatment is started early.

Heat, particularly moist heat, has its place and is of considerable utility when it is a question of aiding Nature to remove inflammatory products and when the acute process is at an end, as, for instance, after crisis

in lobar pneumonia or for the elimination of serous exudates. Cold, on the other hand, is indicated in the majority of acute ailments, but it should be remembered that the selection of the form of cold to apply is of the greatest importance in the physiologic effect produced. A cloth wrung out of cold water and applied to an inflamed area produces at first a certain amount of nervous shock, absorbs heat, contracts the blood vessels and thereby lessens congestion. Removing this cloth, wringing it out from cold water and again replacing it creates a distinct irritation or stimulation of the parts, a process of reaction, an increased blood supply and a dermic stimulation that is frequently undesirable, particularly when the inflammation is caused by bacterial invasion. In all such cases the object should be to apply a form of cold in which the cooling agent is of constant and lasting degree and in which the degree of cold is one that will help to retard or to check bacterial growth, to relieve congestion and pain and at the same time do no injury to the vitality of the parts covered. Uniform currents of cold water, cold air, the use of liquid air, freezing mixtures, etc., have all been tried, but no form of cold is more simple and better suited for the purpose than melting ice, when properly applied.

In order to apply melting ice properly the ice-bag should be one that is provided with a drainage tube, so that the water from the melted ice is constantly drained off, and in which the degree of cold used is constant, thereby utilizing the enormous amount of heat required to liquefy ice, the difference between melting ice and ice-cold water as a heat-absorbing agent being as 80 to 1, measured by calorimeter in centigrade degrees. The importance of drainage in ice-bags, therefore, is evident. Without such provision ice-bags, soon after their application, become more or less filled with water and air, forming a rolling body hard to keep in place, which gives only the effect of cold water—so greatly inferior to that of melting ice. A drain ice-bag filled with crushed ice to such an extent only that its weight can cause no obstruction to the circulation of the parts to be covered is the ideal form of ice application. Such an ice-bag, when water and air are pressed out at the time of applying it, remains collapsed and holds the ice between the walls of the bag by the outer pressure of the air and, furthermore, retains any shape given it till the ice is melted. Thus it can readily be made to fit the head, neck, chest, abdomen or a joint.

Of diseases in which the application of ice-bags is of great importance as an auxiliary remedy the following may be mentioned: Acute meningitis, acute mastoid disease, acute tonsillitis, lobar pneumonia (with marked success), acute pleurisy, acute endocarditis and myocarditis, acute hepatitis, acute gastritis, acute rheumatic arthritis and acute synovitis, acute enterocolitis, acute peritonitis and acute pelvic diseases, acute cystitis, acute appendicitis (of great benefit), hemoptysis, hematuria, typhoid fever (to head and abdomen), scarlet fever (to head), erysipelas (to region involved), neuralgia, headache, etc.

My drain ice-bag and specially designed pneumonia bag now in use at many hospitals are shown in the accompanying illustrations.

SCHISTOSOMA HEMATOBium IN THE CANAL ZONE.

M. EARLE HIGGINS, M.D.

ANCON, PANAMA.

The following cases of infection, with the blood fluke, *Schistosoma hematobium* (bilharzia), occurring in routine stool examinations, would indicate that this parasite is not an uncommon one in the Canal Zone, particularly among the negro laborers from Martinique:

CASE 1.—Martinique negro; male. On Isthmus one month (Culebra). Admitted Dec. 2, 1905, with lobar pneumonia.

Stool: Ova of bilharzia and uncinaria.

Blood: On admission this was negative for malaria; nine days after crisis leucocytes were 9,500; hemoglobin, 40 per cent.

Urine: During the height of fever there was a slight trace of albumin, with a few hyaline and granular casts. Albumin and casts disappeared before discharge. Sedimented specimens showed no blood or ova.

There were no bladder symptoms.

CASE 2.—Martinique negro; male. On Isthmus one and one-half months (Panama). Admitted Dec. 10, 1905, with malaria and bronchitis.

Stool: Ova of bilharzia and uncinaria; *Tricomonas intestinalis*.

Urine: Negative; sedimented specimens.

No bladder symptoms.

Blood: Ameboid rings; estivo-autumnal parasites; leucocytes, 4,200; hemoglobin, 35 per cent.

CASE 3.—Martinique negro; male. On Isthmus three months (Paraiso). Admitted Dec. 12, 1905, with anemia.

Stool: Ova of bilharzia and uncinaria; embryos *Strongyloides stercoralis*; a few red blood cells.

Blood: Leucocytes, 9,300; hemoglobin, 77 per cent.

Urine: Negative. Centrifugalized specimen showed no ova or blood.

No bladder symptoms.

CASE 4.—Martinique negro; male. On Isthmus two months (Paraiso). Admitted Dec. 22, 1905, with anemia.

Stool: Ova of bilharzia, uncinaria, *Trichocephalis dispar* and *Ascaris lumbricoides*.

Blood: Leucocytes, 5,800; hemoglobin, 57 per cent.

Urine: Negative.

No bladder symptoms.

An interesting feature of these cases is that they were all benign; none of the patients apparently suffered any inconvenience from the presence of the parasites. Ova of the *Uncinaria americana* or *Anchylostoma duodenale* (both parasites occur here) were associated with every case, and probably produced the concomitant anemia. None of the patients presented any bladder symptoms, and no ova or blood was observed in the urine (microscopic examination of sedimented specimens in three cases and of centrifugalized specimen in one case).

A careful examination of the rectum of each patient showed no appreciable ulceration or polypoid growths.

The ova corresponded to the usual descriptions, and in every instance the characteristic spine was laterally situated—a point which Manson suggests may indicate a distinct variety of the parasite, with oviposition only in the bowel. In Cases 2 and 4 the ova were fairly numerous, two or three occurring in each cover-slip preparation. In the other two cases they were less frequent—one ovum to two or three preparations.

Brem, who first observed the ova at this hospital, saw the following three cases:

CASE 5.—Martinique negro. On Isthmus two months. Past history of painful urination and hematuria. While in the hospital he had a cystitis with retention.

Stool: Ova bilharzia and uncinaria; blood, pus and mucus.

Urine: Sedimented specimen showed numerous pus cells, but no ova or blood.

Defecation was painful.

CASE 6.—Martinique negro.

Stool: Ova of bilharzia and uncinaria; no blood.

Urine: Sedimented specimen, no ova or blood.

CASE 7.—Venezuelan.

Stool: Ova of bilharzia and uncinaria; no blood; large un-known ciliated monad.

No bladder symptoms.

Urine: Negative for albumin; no microscopic examination.

While six of the seven cases were in negroes, who had recently come to the Isthmus from Martinique, the occurrence of the parasites in the Venezuelan shows that the infection is not confined entirely to the former country.

A NEW AND PHYSIOLOGIC EXPLANATION OF A COMMON PSYCHOLOGIC PHENOMENON.

F. PARK LEWIS, M.D.
BUFFALO, N. Y.

On first viewing an unfamiliar scene many people have, doubtless, experienced the curious sensation of having seen it before. This may have been obviously impossible. It may have been in a part of the world visited for the first time and yet there is a feeling so haunting in some instances as to be distressing—that it is all a repetition of something that has occurred in the indefinite past.

This is a phenomenon so common that various theories have been offered in explanation. The most commonly accepted is that of the psychologist, who tells us that at the instant of the

first glance the mind is pre-occupied and that a space of time, which may be infinitely minute and imperceptible, elapses before the intelligence can grasp the meaning of the sensual impression and interpret it into a cognizable fact. In the realm of the subconscious there is no measure of time—as on the limitless ocean or in infinite space, there is no estimate of distance. One mental impression bears the relation to another mental impression which is not consensual with it, as being merely before or after, but how long, before or after, the mind is incapable of determining. The conscious sensation conveyed to the intelligence is merely that at some former indefinite period, which in point of fact is an infinitely small space of time, although it may seem years away, the same mental picture had been presented as that which is now obviously evident. Almost coincident, then, with the view is the impression of a former view, and as they are not perfectly blended the one is associated with the memory of the other. That we have no estimate of time in our subconscious state is shown in dreams. Here we seem to pass through years in time that is measured by seconds. The well-known illustration will be recalled of a man who dreamed that he had enlisted in the British Army—was sent to India—served through many experiences—deserted—was recaptured—tried by court-martial—sentenced—led out for execution—placed before the detailed squad and a volley fired. He had been asleep less than a moment and the same noise which had aroused him had excited the long and involved dream.

Recognizing the fact that the conscious intelligence is unable to form any judgment as to the length of time that intervenes between two sensual impressions that follow in quick succession, a more logical explanation than the accepted one can be given of this not uncommon phenomenon.

In order that a clear and definite picture of that which we see may be conveyed to the brain, the two retinal images must be blended at the cerebral visual centers as the two views of a single scene are blended by a stereoscope. In order to have an efficient working instrument, the stereoscopic lenses must be focused alike; and to have a binocular blending of images in the more delicate focal adjustments which are governed by nervous action and muscular effort the eyes must be alike.

According to the experiments of Sulzer, of Paris, based on the discoveries of experimental physiology, the accommodative act in the normal human eye is accomplished in about 2/100 of a second. In the hyperopic or astigmatic eye, in which greater muscular effort is required to focus the visual rays on the retina, manifestly the accommodative act would be produced less quickly. In cases in which the two eyes are definitely unlike the focal acts are not coincident, and it may easily take 4/100 of a second, or twice the length of time that is required by the more nearly normal eye for the less perfect eye to define the retinal picture and convey its impression to the cortical sight center. An interval of 2/100 of a second would thus intervene between the times that the same picture was focused on the two retinae and received by the brain, an interval too short to be recognized by the individual but long enough to give two distinct impressions to the mind with a vague, an indeterminate, an immeasurable space of time between.

It is very probable that auditory differences of a like character may sometimes exist, but even when this does not occur, when, owing to refractive differences in the eyes, the faculty of concomitantly blending sensual impressions into intellectual conceptions has been lost, the habit of synecopating impression (if the term might be employed in this connection) will have obtained, and the brain will receive a double impression, whether the images are of visual or auditory character.

That this explanation is a correct one finds its verification in the fact that those to whom this phenomenon is of common occurrence find that it disappears when focal differences are corrected by proper glasses, permitting thereby concomitant action on the part of the ciliary muscles of both eyes.

It will be seen, too, that refractive differences, when marked, and in those of especially unstable nervous dispositions, may cause a mental confusion which is also relieved by the visual correction. Such a case, found in a state hospital for the insane, in my clinic, was cured by a correction of the refractive and muscular inequalities.

As this is a new as well as a rational and physiologic explanation of a common phenomenon, and one easily submitted to a demonstrative test, I will be indebted for any verifications with which I may be favored in which this sense of double impression disappears after a refractive correction. I will be glad, too, to receive a copy of the prescription showing the refractive differences in the eyes.

THE DIRECT READING OF ACIDITIES OF GASTRIC CONTENTS.*

GEORGE WILTON MOOREHOUSE, M.L., M.D.

CLEVELAND, OHIO.

In the quantitative determination of the acidity of gastric contents a decinormal solution of sodic hydrate is usually employed. Each cubic centimeter neutralizes an acidity equivalent to .00365 gm. of hydrochloric acid. Six cubic centimeters is ordinarily considered an average amount to neutralize the total acidity of 10 cubic centimeters of normal contents. The acidity of gastric contents is most commonly expressed by multiplying by 10 the total number of cubic centimeters of $N/10$ NaOH required to neutralize 10 cubic centimeters of gastric contents. A normal total acidity is, therefore, about 60. The solution of sodic hydrate, however, is not permanent; should it be accurate when received from the chemist it will not be accurate after a few days, and the variations may be considerable to one using it infrequently.

To minimize the difficulties imposed by constant change in the concentration of sodic hydrate solutions some workers determine at frequent intervals the value of their solutions of alkali, and express the acidity of gastric contents in grams per hundred or per thousand. This involves titration and computation as frequently as necessary to determine the value of the sodic hydrate solution; titration and computation to express the result in grams per hundred or per thousand, and a further computation before it is possible to express the result in the terms which are more generally understood and more easily remembered. It is probable, however, that a considerable number of those who express the results in the simpler form replace their solutions at whatever intervals they consider necessary to insure sufficient accuracy, and always consider the value of the solution to be .00365. Such renewal of solutions is an unnecessary expense, since the titration of the alkaline solution to determine its value is hardly more troublesome than sending the bottle to the chemist for standardization would be.

The use of the accompanying diagram makes accurately decinormal solutions of sodic hydrate and computations unnecessary in quantitative examinations of the acidity of gastric contents. With sufficient frequency, about once a month, the number of cubic centimeters of alkaline solution to neutralize 10 cubic centimeters of a true decinormal acid solution should be determined and recorded. In use with gastric contents, it is necessary only to determine the amount of alkaline solution in cubic centimeters to neutralize, first, the free

hydrochloric acid of 10 cubic centimeters of the gastric contents, and, second, its total acidity. With these facts determined, the acidity of the gastric contents may be read from the diagram either in grams per thousand or as 60, 70, etc., the more common method of expression.

The vertical lines represent the number of cubic centimeters of a $N/10$ NaOH required to neutralize the 10 cubic centimeters of decinormal acid solution. The horizontal lines represent the number of cubic centimeters of this solution of alkali required to neutralize 10 cubic centimeters of gastric contents. On the diagonal, passing (actually or by interpolation) through the point at which these lines cross, may be read off the acidity of the gastric contents, both methods of expression being given.

Examples: If 10 cubic centimeters are required to neutralize the decinormal acid solution and 6 to neutralize the gastric contents, follow the vertical line 10 down to the line 6. Where these lines intersect a diagonal line may be found which is marked 60 and 2.19. This means that the acidity of the gastric contents is 60, or, expressed in terms of hydrochloric acid, contains 2.19 gm. of acidity to each thousand cubic centimeters of gastric contents.

Amount in c.c. of the $N/10$ NaOH to neutralize 10 c.c. of a decinormal acid solution.

If but 6 cubic centimeters of the sodic hydrate solution are required to neutralize 10 of the acid and 8 of this alkaline solution are required to neutralize 10 of the gastric contents, follow the vertical line 6 to the point where it is crossed by the horizontal line 8. This brings one between the diagonals 130 and 140, and about one-third of the distance from the lower to the upper diagonal. The acidity is about 133 or 4.877 gm. per mille.

Should 12.5 cubic centimeters of the $N/10$ NaOH be required to neutralize 10 of the decinormal acid and 6.3 cubic centimeters of the former be required to neutralize the gastric contents, the result is 50 or 1.83 gm. per mille.

The accuracy of the diagram has been tested in a number of ways, and the average error in its use seems to be too small to be of any consequence. It is constructed for normal to 1/20 normal sodic hydrate, and for acidities from 0 to 170—from the lowest free hydrochloric to the highest total acidity.

MEDICAL AND LIBERAL EDUCATION.

All who have been striving to promote solid progress in the American medical profession have taken great interest in the recent efforts to make possible the combination of liberal education, as represented by a preliminary college degree in arts and science, and the exacting requirements of present day medical education. From the comparative low standard of fifty or more years ago, the requirements for admission to college and for obtaining the degree have been gradually and steadily increased until the average age for graduation has been increased two, three or even more years. The graduate of fifty years ago was no more advanced than the present sophomore and besides this the requirement for admission to college was much less exacting. Moreover, at least two additional years have been added to the time required for medical study and this is not optional, but required by state laws, much to the benefit of the standing of the medical profession. As a result of these increased requirements it is seldom possible for a man to get the liberal education represented by a college degree and to take the four years required in medicine before twenty-seven or twenty-eight years of age, and the man does not reach his period of useful activity until he is nearly thirty years old. The increase in time is so great that many men at present do not even try for a liberal education.

That this postponement of a man's practical usefulness should be cut down to two or three years and still leave him the advantage of liberal culture at college is generally admitted. To accomplish this various plans have been suggested. Chicago, Cornell, Michigan, Columbia and a number of other institutions have arranged a combination of courses by which the student may take a degree both in science or arts and in medicine in one or two years less time than the eight years regularly required for both degrees taken separately. Among the institutions not having a medical department, Wabash College allows its students to enter an approved medical college after three years of study and grants the degree in arts at the end of the first year of professional instruction. The cutting down of the required college course from four to three years for all students has been urged on several sides of late. This would not be so great an innovation, however, for Johns Hopkins Uni-

versity has required of its art students only three years of study, and with a liberal range of electives from the start, and for years Yale has maintained a three years' course in its scientific school. At Harvard the present system gives an opportunity to take the degree in three years, and about 15 per cent. of the student body avail themselves of this. We are told that the change has not lowered the standard nor lessened the distinction of the degree.

The discussion of a three years' course as the normal for the degree in arts has recently been taken up at the meeting of the Associated Harvard Clubs and a sixty page report prepared, giving the opinion of the graduate body on the practical side of the question and the actual bearing of period of residence on after life in the professions and in business, specially in the West. The counting of the first year of professional study as the fourth year in college is thought objectionable because it forces the student to discriminate in favor of the professional school connected with the university in which he takes his arts degree, for they consider it desirable that he should choose independently. An abstract of the report, published in the *Harvard Graduates' Magazine*, 1905, vol. xiv, p. 95, will be of interest to all who have been following these questions. There has undoubtedly been a falling off in the proportion of the college educated men taking up the study of medicine and by cutting down the liberal course of study the number would no doubt be somewhat increased again. European experience, where secondary schools are highly organized and well conducted and professional education amply developed, all indicates that four years of liberal study can not be maintained between the school period and the period of professional study. The standards of the secondary schools should be improved and it would not be difficult to prepare the average student for college at least two years earlier than is usual at present. If this were arranged, with the cutting off of one year from the college course, it would be possible for students to graduate in both arts or science and medicine at twenty-four, instead of two or three years later, as is now usually the case. The shortening of the course of liberal study seems more justified from the reason that the mental discipline of the professional course is more valuable than formerly. The shortened course would also tend to lessen the excess of attention given to athletics and indulgence in other diversions injurious to proper attention to study, without depriving the student of reasonable opportunity to enjoy ideal college life. Three years of undergraduate study is sufficient to give the general culture, which is the object of college education, and three comparatively strenuous years are better altogether than the present four years of lax effort.

Whether the suggestions of the committee of the Associated Harvard Clubs will lead to any change of policy by Harvard University will remain to be seen. But the fact that the report of the committee includes letters

and interviews from over fifty persons in business and professional life indicates a live interest in the problem by busy men. Those of the medical profession, who have had the advantages of collegiate training, are general advocates of similar liberal studies for others; and, no doubt, whether these changes are introduced or not, a great proportion of the coming leaders of the medical profession, as in the past, will precede their medical studies by a college course. That the efficiency of education need not suffer by an arrangement which would shorten the course two or three years, we feel sure, and any arrangement that would bring about such an end would undoubtedly be welcomed by students.

EXPERIMENTAL EOSINOPHILIA.

There are two opinions in regard to the relationship between the various forms of white blood corpuscles, the one maintaining their genetic distinctness, the other that transition is easy from one form to another, and well-known hematologists are arrayed on either side.

On account of the large size and the staining properties of their granules, the eosinophilous leucocytes have served as the basis of more study than other forms. Their increase in the blood in certain diseases has considerable importance in diagnosis; as is well known, in trichinosis, for example, eosinophilia is very characteristic, but it may occur in other forms of helminthiasis as well. The behavior of eosinophiles in bacterial infections has long been the subject of investigation, and it has been ascertained that in some infections an increase of eosinophiles indicates a favorable outcome, while diminution in number has the contrary significance. In spite of the many researches these cells have instigated, their origin and their granules still present many problems.

It has been generally taught that the eosinophiles, in common with other leucocytes, are produced in the hematopoietic lymphoid structures, especially the bone marrow; that their appearance in the blood in larger numbers than normal is due to a chemical attraction caused by substances or alterations in the fluids of the blood, and their great excess over other forms of leucocytes in the tissues in certain inflammations and tumors, the so-called localized eosinophilia, has also been explained by chemotaxis.

Now the similarities in appearance and reactions to dyes of the erythrocytes and the granules in the eosinophilous leucocytes have led to suspicions that there might be a genetic connection between the two; indeed, it was once supposed that the red cells were derived from these granules. The exact converse of this, the origin of the granules from the red cells, is also an old idea, but one which has met with little acceptance because of the prevalent belief in the distinct origin and specific nature of each form of leucocyte and their inability to be transformed, one into another.

It is, therefore, of great interest to have rather convincing evidence offered in favor of the assumption that the granules in eosinophilous leucocytes consist of hemoglobin derived from the red corpuscles; in a word, that eosinophiles are essentially phagocytes; and a point of view is presented that may lead to quite radical alterations in our ideas of leucocytes.

Sischastnyi finds a marked eosinophilia in animals a few days after the intraperitoneal injection of either normal alien serum or alien serum with increased hemolytic properties, the so-called immune serum.¹ The presence of eosinophiles in the peritoneal cavity, in the omental vessels and vessels of other adjacent structures in greatly augmented numbers preceding the development of a generalized eosinophilia led him to trace the origin of the eosinophilia in the phagocytosis of erythrocytes, terminating in eosinophilous leucocytes by unbroken transitions, which followed the injections. Phagocytosis was also present in the bone marrow, and here also the eosinophiles were increased in numbers. These experiments indicate, therefore, that the eosinophilia is an expression of the manner in which the organism disposes of its own red corpuscles.

This explanation of the experimental eosinophilia caused by hemolytic sera may throw some light on the increase of eosinophiles observed, for instance, in hemorrhagic pleuritic exudates; also on the eosinophilia appearing after the acme of numerous infectious fevers and on the repeated occurrence of eosinophilia in the afebrile stages of the malarial fevers. It is noteworthy in this connection that phagocytosis of red corpuscles is a part of the histologic changes in many infections. The study of hemolysis has been, for the most part, the study of the solution of the red blood corpuscles of one species by the blood serum of another, a field apparently quite removed from practical medicine. These observations of Sischastnyi must be added to the list, already a long one—many examples have been considered in these columns—of instances in which light has been thrown unexpectedly on obscure processes of spontaneous disease by the study of hemolysis.

"SPIROCHLETA PALLIDA" IN HEREDITARY SYPHILIS.

"*Spirochæta pallida*" has been demonstrated in the organs of hereditary syphilites by a number of observers. Just recently Levaditi publishes an important contribution to this subject,² in which several interesting facts are brought to light. Thanks to an improved staining method (impregnation of small pieces of formalin fixed tissue with silver nitrate, reduction with pyrogallie acid, and counterstaining), Levaditi is able to establish more clearly the relations of the spirochete to the lesions in hereditary syphilis than heretofore possible. He shows that organs and tissues most involved in the syphilitic process contain the largest number of organisms, namely,

1. Ziegler's Beiträge, 1905, vol. xxxviii, p. 456.

2. Ann. de l'Inst. Pasteur, 1906, vol. xx, p. 11. See p. 917.

the liver, the lungs, the adrenals, and the skin, in the order given, thus demonstrating the rôle of the spirocheta to be more important than that of a mere secondary invader.

In acute, rapidly fatal cases the parasites are more diffusely distributed, in the chronic, tardy cases they are present mostly in the organs affected, e. g., the liver. The parasites appear to become arrested first in that fetal organ, namely, the liver, which is the first to receive the blood as it comes from the placenta. Levaditi pictures spirochetes in the lumen of the hepatic vessels in certain cases; the organisms do not appear to multiply in the blood, however, but to pass into the perivascular tissues and the glandular epithelium. There result endarteritic and periarteritic processes, infiltrations and sclerosis of the connective tissue, and parenchymatous degeneration, all due, it would seem, to the direct action of the organisms themselves, which are present in enormous numbers, rather than to the diffusion of soluble products. The maceration of the syphilitic fetus after intrauterine death is regarded by Levaditi as the result of a widespread secondary autolytic effect and not as due directly to the spirochetes. The presence of organisms within large phagocytic cells, especially in the pulmonary alveoli, would seem to indicate that phagocytosis is an important means of defense against this virus and especially because the organisms are seen to undergo disintegration within the phagocytes. The presence of spirochetes in the lumen of bronchi and also in the renal epithelium indicates that the sputum and also possibly the urine may be infective in hereditary syphilis. Another source of infection is seen in the skin, the papillæ of which, as well as the contents of Pemphigal vesicles, may harbor well-preserved spirochetes.

In doubtful cases the demonstration of *Spirocheta pallida* may settle the diagnosis if, as seems to be the indication, this organism comes to be accepted as the causative agent of syphilis. Already interesting questions suggest themselves as to the mode of infection in congenital syphilis, especially in those cases which we now regard as paternal and conceptional.

THE ZEISS OPTICAL WORKS.

Few of us who use the admirable microscopes which bear the name of Zeiss realize that when we buy one of these instruments we are encouraging a most novel and daring, if not revolutionary, industrial experiment. Carl Zeiss and his partner, Ernst Abbe (the inventor of the Abbe condenser) are not known to the scientific world as altruistic dreamers, yet the record of their experiment in profit sharing and in the application of democratic ideals to industrialism reads almost like the optimistic visions of a Bellamy.

The Zeiss optical works were started in a humble way in Jena as long ago as 1816 under Carl Zeiss, who later, in 1875, took as partner Ernst Abbe. From the first Zeiss seems to have planned the organization of the

industry on a co-operative basis, with the guarantee of personal liberty to the employés in all political matters, an unusual departure in Germany at that time. His views, however, were not fully realized during his lifetime, but were developed after his death by Abbe, a man of singular unselfishness and idealism. At Zeiss' death, in 1896, the entire capital invested in the now enormous business was left in Abbe's hands and he handed it over to an organization, the "Carl Zeiss Stiftung," which is established under the laws of Saxony with a trustee appointed by the State to supervise it. For himself Abbe reserved only the modest income of \$2,500 a year up to his death, which occurred a short time ago. The 1,300 employés, most of them highly skilled artisans, form now an association which undertakes the management of the business through committees, their avowed object being the payment of wages, not the making of profits.

The management of the works follows principles which would seem to us socialistic in the extreme. There is a regulation that the highest paid official shall not receive more than ten times the average yearly earnings of the average adult workman. An employé who has reached a certain yearly rate of wages can not after that receive any less sum on account of slack times. Most remarkable of all, in case of dismissal for no fault, after three years' employment, the workman receives at least six months' pay. Of course, there are minor advantages, such as the eight-hour work day, holidays on full pay, grants for buying homes, insurance against sickness and death, premiums for new inventions and labor-saving devices of all kinds. These apparent extravagances, however, do not prevent the company from making profits, which profits are partly distributed among the workmen, the rest being used for extension of the works, for grants to the University of Jena, and for institutions of social amusement and education for the workers themselves. The influence of Carl Zeiss is seen especially in the provision which makes it possible not only for the artisan to join any party or trades union that he may choose, but which encourages him to hold office under the local or imperial government, granting him leave of absence on full pay for the time required to perform his public duties.

Whatever we Americans may think of the ideals of Zeiss and Abbe we must admit that their experiment, now fully ten years old, has proved itself a success in the business world and that the product of this utopian factory has probably no equal anywhere.

VIVISECTION.

A correspondent has sent, for examination and comment, a pamphlet entitled "Illustrations of Human Vivisection," published apparently in Chicago by the "Vivisection Reform Society," an organization the avowed purpose of which is to make vivisection experiments a crime, except when under legal regulation.

While the tone of the pamphlet is generally unjudicial and the author seems to have a strong personal bias against at least one prominent member of our profession, we are willing to assume for present purposes that ignorance, and not wilful malice, must have been the cause of some of his illegitimate inferences, not to use another designation. We would therefore say, for his information, that, in accounts of physiologic experiments, "toxic" does not mean lethal or even necessarily dangerous; that "inoperable," from a standpoint of cure, does not mean that operation to prolong life or to make the remnant easier is unjustifiable; that the administration of pain-relieving drugs to neuralgic soldiers is not inhuman, even if the pulse and pupils were observed, and that it would be usually considered very mild treatment for military malingerers. Forty years ago comparatively little was known of the antagonism of atropin and morphin, and such observations were valuable and the world has profited by them ever since. Other suggestions might be made, but we have probably gone sufficiently out of our way now to set the author of the pamphlet right. It is to be hoped that he will be more careful in the future in his inferences and deductions. *THE JOURNAL* is in full accord with every right-minded person in denouncing reckless experimentation, but it does not expect to suit some of the antivivisectionists who, ignorantly or otherwise, reject facts when these do not conform to their theories.

GOOD RAILROAD RATES FOR THE BOSTON SESSION.

The Trunk Line Association, covering the eastern railroads, as well as some of the other passenger associations, have granted a rate of one fare for the round trip, plus \$1.00, for the coming session of the American Medical Association. Undoubtedly all of the other passenger associations will take the same action, so that we may depend on one-half rates from all parts of the country. An extension of time to June 30 will be granted on payment of \$1.00. Those coming from the Pacific Coast points can have an extension of return limit up to August 31. This concession to our friends on the Pacific Coast is made, of course, on the supposition that, after coming so far, they will want to take advantage of the trip to visit friends or to see the attractions of the east. Efforts are being made to secure such arrangements that one may go by one route and return by another, as was the case last year. Whether or not such concessions will be granted on the half-rate fare is yet to be decided.

LEGISLATION TO PREVENT THE SALE OF UNDRAWN POULTRY.

Senator Gallinger has introduced into the United States Senate a bill making it "unlawful for any person, firm or corporation to sell, offer or expose for sale, within the District of Columbia, any poultry, refrigerated or otherwise, which has not been properly drawn and prepared by removing the viscera at the time of slaughter." Violation of the act is punishable by a fine not exceeding one hundred dollars, or by imprisonment not exceeding thirty days, or both. The bill was referred

to the Committee on the District of Columbia and by that committee recommended for passage. The necessity for such legislation will be recognized by those who have given the matter thought. The keeping of meats, eggs, vegetables, fruits, etc., in cold storage has grown to such enormous proportions that it would seem that in the large cities the greater bulk of our foods is being so preserved. To what extent such foods are injurious or are depreciated in their food value has not been sufficiently investigated to come to definite conclusions, but undoubtedly many articles so preserved do depreciate in many ways and become a danger to health.

THE AUTOMOBILE NUMBER OF THE JOURNAL.

To no one class of people is the automobile of more practical importance as a business proposition than to physicians. Whether in the city or country, the physician needs a means of quickly, safely and surely reaching his patients—and of getting home again. On account of this general interest of physicians in the subject, it is believed that a special number of *THE JOURNAL* devoted to a discussion of the automobile as a conveyance for physicians will be of practical interest and will be welcomed. We have had such a number in hand for some weeks, and have already received a large number of articles on the subject, but we shall be glad to hear from any physician who has had practical experience and who has not already written us. We want both sides. The expense and the difficulties connected with the machine as compared with the horse, the type of car most practical, technical points connected with gears, transmissions, cylinders, fuel, cooling apparatus, tires, etc., are important items for discussion. Articles must be brief, terse and to the point, as the space devoted to the subject must necessarily be limited. All manuscripts should be received by April 2. The date of issue will be April 21.

QUININ IN PNEUMONIA.

It is possible that in emphasizing a certain point in the editorial under the above title in last week's issue we may have been misunderstood, for we came very near to actual overstatement. We said: "In private practice it is no uncommon thing for a busy physician to treat 40 to 50 consecutive cases of pneumonia by the so-called expectant or symptomatic plan, and to have no deaths." It would have been better if we had said that "it may occasionally happen that a physician with a large practice," etc. Undoubtedly, in private practice, and more rarely in hospitals, a considerable series of favorable cases may be met with, especially in the young, and in these cases an unusually favorable outcome may result. We would not imply that the mortality from pneumonia is low, for we have repeatedly shown that the total mortality from this disease is pretty nearly as high as that from tuberculosis. Dr. E. F. Wells published some statistics some time ago in which it was shown that the mortality from pneumonia was 18.1 per cent. This was based on a study of 233,730 cases.¹ We repeat that

¹ E. F. WELLS: *THE JOURNAL*, A. M. A., 1902.

we welcome any contribution to the subject of treatment of this disease that is based on a careful study of a number of cases, whether by the treatment recommended by Dr. Galbraith or by that which recognizes the disease as a self-limited one and that the *vis medicatrix nature* will bring about a cure in the majority of instances.

Medical News

COLORADO.

New Hospital.—The new City Hospital, La Junta, was opened February 12.

Fire in Medical College.—Fire did damage to the amount of \$10,000 to the Denver and Gross College of Medicine January 30.

Will Erect Dispensary.—The Denver and Gross Medical College will shortly erect a dispensary on two lots adjoining the College of Music at Fourteenth and Arapahoe streets.

Physician Gets Damages for Injury.—A verdict of \$5,500 was rendered against the Inter Mountain Improvement Company in favor of Dr. Fred H. Welles, Victor, who had his left leg and foot crushed between the elevator and the wall of the shaft in a building owned by the defendant, in 1902. He sued for \$50,000 damages.

Eastern Practitioners Meet.—The Eastern Colorado Medical Society held its annual meeting January 9 and 10 at Wray, and elected the following officers: President, Dr. Earl D. McGill, Wray; vice-presidents, Drs. W. E. Turner, Brush and George B. Bilsborrow, Yuma; secretary, Dr. S. S. Bootay, Akron, and treasurer, Dr. N. J. Phelan, Denver.

Personal.—Dr. Frank N. Carrier, Canon City, has been appointed physician of Fremont County; Dr. James W. Rambo, Florence, assistant county physician, and Dr. Wilbur T. Little, Canon City, county health officer.—Dr. F. L. Bartlett has been elected president, Dr. John W. O'Connor, vice-president, and Dr. William H. Bergtold, secretary, of the Colorado Automobile Club, Denver.—Dr. Michael Beshoar, Trinidad, after thirty-three years, retired from active practice February 25.

January Vital Statistics.—During January 939 deaths were reported, equivalent to an annual death rate of 16.8 per 1,000. Scarlet fever caused 13 deaths; typhoid fever, 12 deaths, and diphtheria, 8 deaths, during the month. There were reported during the month 179 cases of scarlet fever, 75 cases of typhoid fever, 49 cases of diphtheria, and 26 cases of smallpox, an increase, as compared with the preceding month, of 60 cases of scarlet fever, 8 cases of typhoid fever, 1 case of diphtheria, and 16 cases of smallpox.

DISTRICT OF COLUMBIA.

Smallpox. The smallpox situation in the District is becoming serious. All the cases are said to be traceable directly to cases erroneously diagnosed, which remained unquarantined.

—Dr. Arthur C. Stanley, an interne at Garfield Hospital, is ill with smallpox.

Banquet in Honor of Dr. Hare. The Clinical Society of Washington gave a banquet March 10, the guest of honor being Dr. Hobart Amory Hare, Philadelphia, who delivered an address on "The Relation Between Diseases of the Heart and Diseases of the Arteries."

Hospitals Get Money. By the verdict of a jury in the Probate Court, March 6, the will of the late Dr. Henry E. Woodbury, which bequeathed the bulk of his estate, valued at about \$35,000, to the Garfield Memorial Hospital and the Children's Hospital, share and share alike, was sustained.

Want a Clean River. A determined effort is being made by the officials of the Army Medical Department, Public Health and Marine Hospital Service, Medical Society of the District of Columbia, and other organizations, to prevent the pollution of the Potomac River and to improve the sanitary conditions.

FLORIDA.

State Health Officer Indorsed. By a unanimous vote the Jacksonville Board of Trade adopted resolutions expressing implicit confidence in Dr. Joseph Y. Porter, Key West, state health officer, and urging him to withdraw his resignation. Similar resolutions were adopted by the Key West Chamber of Commerce.

Hospital Closed.—The Emergency Hospital, Jacksonville, was closed February 1 owing to the failure of the city council to make provisions for its maintenance.

Personal.—Dr. and Mrs. Percy J. Stollenwerk, Jacksonville, have returned from Europe.—Dr. George W. Lamar, Quincy, has been appointed by the governor, medical superintendent of state convicts.

Mental Healer Imprisoned and Fined.—After a trial of twelve days Helen M. Post, head of the Mental Science Institute, Sea Breeze, an "absent treatment" institute, was found guilty, February 3, of using the mails for fraudulent purposes and sentenced to pay a fine of \$500 and to be imprisoned for thirty days in jail.

New Sanitaria Completed.—The Centro Espanol Sanitarium on the bay shore, Tampa, erected by the Spanish colony of that city and presented to the city of Tampa, was dedicated February 4.—The De Soto Sanitarium, Jacksonville, which is owned and operated by local physicians and has a capacity of 50 patients, is now open to the public.

GEORGIA.

Damage by Fire.—Dr. B. J. Simmons, Milledgeville, lost \$1,000 by a fire which did severe damage to the business portion of the city, February 1.

New Laboratory Installed.—The new municipal laboratory, Atlanta, has been installed in the City Hall and is under the charge of Dr. Claude A. Smith, city chemist.

Historic Building Demolished.—The historic old medical college building, Atlanta, which was pressed into service during the Civil War as a Confederate hospital, is being torn down to make room for the new building of the Atlanta College of Physicians and Surgeons, to be erected at a cost of \$75,000.

Personal.—Dr. Thomas R. Wright, Augusta, has been re-elected a member of the governing board of the city hospitals.

Dr. Joseph E. Allen has been elected dean of the faculty of the Medical College of Georgia, Augusta, to fill the vacancy caused by the death of Dr. De Saussure Ford.—Dr. Edward Geddings has been elected emeritus professor of physiology and pathology in the Medical College of Georgia, Augusta.—Dr. George Brown, Atlanta, assistant surgeon general, has been commissioned colonel and surgeon general of the National Guard, Georgia, vice Dr. Joseph A. Guinn, Conyers, retired.—Dr. Samuel H. Green, Chattahoochee, has been commissioned captain and assistant surgeon, National Guard of Georgia, and assigned to the Fifth Infantry.—Dr. Joseph J. P. Bowdoin has been elected mayor of Adairsville.—Drs. William W. Owens, Savannah, and A. P. Taylor, Thomasville, have been reappointed members of the State Board of Health.—Dr. John M. Caldwell, Augusta, city physician for the third district, jumped from his buggy when his horse ran away, February 9, and fractured his leg just above the ankle.

ILLINOIS.

Benefaction to Hospital.—Brokaw Hospital, Bloomington, has received \$100,000 from the Brokaw estate.

Accutital. In the suit of Mrs. Arthur Ruckman against Dr. Isaac Moore, Alton, for slander, the jury returned a verdict of accutital.

Smallpox. It is reported that smallpox of mild type has broken out in Freeport. It is supposed that the disease was imported from Lanark.

Books Given to Library.—Dr. Thomas J. Pitner has given 200 volumes to the Jacksonville Public Library, and the sons of the late Dr. David Prince have donated 700 volumes to the same institution.

Physicians Vindicated. In the suit of W. P. Eich, Emington, against Dr. Clarence P. Wikoff, Emington, for damages for alleged malpractice, the physician was completely vindicated, as the plaintiff utterly failed to make a case.

Personal.—Dr. Thomas L. Catherwood, Shelbyville, was stricken with paralysis at his home, March 7.—At the last meeting of the Imperial-Royal Medical Society of Vienna, Dr. Nicholas Senn, Chicago, was unanimously elected an honorary member of the society. Dr. John L. Volton, Bloomington, was elected physician of McLean County, March 8.—Dr. William Hessler, Chicago, has been appointed surgeon in the Alexian Brothers' Hospital.

Dr. McCormack's Itinerary.—Dr. J. N. McCormack, chairman of the Organization Committee and national organizer for the American Medical Association, will spend the month of April in Illinois. In Dr. McCormack's reply to the invitation of Dr.

H. C. Mitchell, president of the Illinois State Medical Society, he urges the importance of securing the attendance of laymen at all meetings. The invitations should include senators, representatives, municipal and county officials, the pastors, tar and teachers' associations, druggists, W. C. T. U. and other clubs, as well as business men generally. He says: "I am discussing the scientific and business affairs of the profession, the 'patent-medicine' question, and other matters of this kind before popular audiences every day, and I find that it enables me to strengthen the profession with the public in a way that has never seemed possible before." The itinerary for Dr. McCormack as now arranged is as follows:

Councilor District 9.—Carbondale, April 2; Mt. Vernon, April 3. *Councilor District 7.*—Centralia, April 4; Decatur, April 5. *Councilor District 8.*—Olney, April 6; Newton, April 7; Champagne, April 12.

Councilor District 6.—Pittsfield, Quincy, April 9; Mt. Sterling, Virginia, Jacksonville, April 10; Carrolton, Carlinville, Alton, April 11.

Councilor District 5.—Lincoln, April 13; Bloomington, April 14. *Councilor District 4.*—Galva, Rock Island, April 16; Mommouth, Macomb, April 17; Peoria, April 18.

Councilor District 2.—Pontiac, April 19; Ottawa, April 20; Sterling, April 21.

Councilor District 1.—Freeport, April 23; Rockford, April 24; Aurora, April 25.

Councilor District 3.—Joliet, April 26; Chicago, April 27-28. The meeting places and other local arrangements will be announced in the various towns and councilor districts by letter and through the local press.

Chicago.

Arrest Spitters.—Acting under orders from the chief of police, a crusade has again been begun against men who expectorate in street cars and other public places.

Hospital for Acute Alcoholism.—Alderman Souly has introduced an ordinance in the city council providing for the construction and maintenance of a hospital for the treatment of acute alcoholism.

Sues Advertising Specialists.—Adolph Siebert on March 12 sued the Auld Medical Company for \$80, which he claimed to have paid under contract that he was to be cured of a disease which had been pronounced incurable by physicians.

Deaths for the Week.—The total deaths from all causes for the week ended March 17 were 555, 52 less than for the previous week and 2 less than for the week ended March 18, 1905. The respective annual death rates per 1,000 were 14.10, 15.44 and 14.57. Pneumonia caused 99 deaths; consumption, 62; heart diseases, 39; Bright's disease, 38; acute intestinal diseases, 30; violence including suicide, 28; and bronchitis, 26. Scarlet fever caused 9 deaths; whooping cough, 2; measles, 1, and diphtheria, 9.

INDIAN TERRITORY.

Hospital Established.—The Willburt Emergency Hospital has been established by Drs. U. A. D. Colchmo, W. H. Horine and Arthur L. Anderson.

Orders Vaccination.—The Muskogee Board of Health has ordered that all school children who can not produce certificates of recent vaccination must be vaccinated.

License Revoked.—The medical board of the southern district recently revoked the license of Dr. R. W. Freeman, Chickasha, on the ground of dishonorable and unprofessional conduct. Dr. Freeman secured a writ of supersedeas and has now brought suit for damages aggregating about \$13,000 against fellow practitioners, who he alleged were responsible for the charges which led to the revocation of his license.

Society Meetings.—The Muskogee Medical Society, at its meeting January 16, adopted a resolution that all regular physicians should take their professional cards from the daily papers and should refrain as much as possible from newspaper publicity. The Medical Clinical Society met at Durant, February 13, and elected the following officers: President, Dr. A. S. Hazood, Sterrett; vice-presidents, Drs. G. M. Rushing, Durant, and W. M. Armstrong, Mead; secretary, Dr. J. A. Humphrey, Durant, and treasurer, Dr. H. W. Yates, Bokshito.

INDIANA.

Epidemic Diseases.—Several hundred cases of whooping cough are reported from Princeton. At Argos, north of Rochester, 172 cases of measles have been reported, with three deaths.

License Revoked.—On the allegation that she has been guilty of criminal practice, the State Board of Medical Registration and Examinations on March 12 revoked the license of Dr. Mary A. Wherry, Fort Wayne.

Goshen to Have Hospital.—The Goshen Medical Society met with Dr. Irvin J. Becknell, March 9, to discuss plans for a city hospital. About \$25,000 will be required for this purpose, \$5,000 of which has been bequeathed by a woman of Denver.

Acquitted.—The jury in the case of Dr. William H. Dings, Mitchell, charged with performing an illegal operation on Carrie Shaw at Mitchell in September, 1904, as a result of which the woman died, returned a verdict of acquittal, February 28.

Newcastle Gets Epileptic Village.—It has been decided that the state epileptic village shall be located in Henry County, near Newcastle. Forty-two towns in the state were applicants for the location. The state paid \$122,882 for the site, or \$100 an acre.

Condemns Criminal Practices.—The Delaware County Medical Society on March 2 passed a resolution calling on the State Board of Medical Registration and Examinations to bar from the practice of medicine all practitioners in the state convicted of criminal practices.

Ross Again in Trouble.—Dr. Nelson B. Ross, Muncie, whose license to practice was revoked on account of gross immorality, was arrested and taken to Newcastle, February 18, on account of an alleged connection with the death of Miss Ethel Hart, Springfield, from an illegal operation.

Physicians Banqueted.—A banquet was given by the physicians of Terre Haute, March 6, in honor of the fifty-fifth anniversary of the doctorate of Dr. Stephen J. Young. A banquet was given by the faculty of the Indiana Medical College, March 1, in honor of Dr. Henry Jameson, dean of the faculty. Dr. John H. Oliver officiated as toastmaster.

Smallpox.—From 15 to 20 cases of smallpox have been reported on the west side of Michigan City. About 20 cases have been reported at English, Crawford County, and the March term of court, which was to have convened at that place March 12, has been postponed. Epidemics of smallpox are reported in Miami and Fulton counties.

Personal.—Dr. Volney S. Cheney has resigned as health officer of Bluffton. Dr. J. B. Seaman, Osceola, who was recently injured in a collision with a street car in South Bend, is improving. Dr. David S. Linville, Columbia City, is seriously ill. Dr. William A. Eschman, secretary of the Anderson board of health, has resigned to accept a position as medical examiner for the Pennsylvania System.

Society Meetings.—Floyd County Medical Society met at New Albany, March 1, and elected the following officers: President, Dr. George H. Cannon; vice-president, Dr. Walter J. Leach; secretary and treasurer, Dr. Dumont Garey; delegate to the State Medical Society, Dr. Elinh P. Easley, and alternate, Dr. J. F. Weathers, all of New Albany. Physicians of Summitville have organized a physicians' club, with the following officers: President, Dr. Winsor Austin; vice-president, Dr. Audley V. Fankboner, and secretary and treasurer, Dr. Etta Charles.

IOWA.

Pure-Food Law.—The legislature has passed a law providing for an annual appropriation of \$10,000 for a pure-food laboratory and other necessary expenses.

Itinerant Physicians.—There are fifteen physicians in the state practicing as itinerants. A list of these is given in the March number of the Iowa *Health Bulletin*.

Mahaska County Medical Society.—At the meeting of the Mahaska County Medical Society, March 13, papers were read by Drs. H. C. Homer, J. G. Roberts and D. C. Brockman. In the evening Prof. Henry Albert, state bacteriologist, gave an illustrated lecture on "Bacteria and Disease," to which the public was invited.

Medical Legislators.—The following are the physician members of the Thirty-first General Assembly, now in session: In the Senate, Dr. Henry Young, Manson; in the House of Representatives, Drs. Mark A. Dashiell, Indianola; Ross H. Gregory, Xenoville; Louis J. Leach, West Branch; George McCulloch, Humeston; L. E. Summers, Milton, and Elbert W. Clark, Grinnell.

Practicing Without License.—A. J. Kendig, Winterset, was tried and convicted in Madison County for practicing medicine without having procured the required certificate. —B. F. Miller, an alleged drugless healer of some denomination, has been indicted by the grand jury of Black Hawk County for violating the medical practice law. The following persons were indicted by the Page County grand jury for practicing

medicine without a certificate: John E. Swanson, Essex; D. W. Humphrey, Shenandoah; John L. Cox, late of Braddyville, and Mrs. Thielen of Clarinda.

Tuberculosis in Iowa.—The board of control of state institutions has just submitted to the legislature its report on the extent of tuberculosis in Iowa and the best means of prevention and treatment of the disease. The report consists of a fifty-page volume and contains considerable interesting information. According to the report there were during the year ending June 30, 1904, 4,569 cases of tuberculosis in the state, as reported by 2,436 out of the 3,532 physicians of the state, no reports having been received from 1,096 physicians in response to blanks sent out by the board of control. Of the 2,436 physicians who reported cases 1,039 had no cases to report. There is no doubt but that there are more than 4,569 cases of tuberculosis in the state. That figure probably represents two-thirds of the total number, if we consider that the physicians who had no report had just as many cases as those who did report. Of the 4,569 cases reported 3,725 were of the pulmonary type and 844 were cases of tuberculosis in other organs. Women are more frequently affected than men, as shown by the figures that 2,611 of the cases were females and 1,957 were males. The following age reports are also of significance: From 1 to 10 years, 332 cases; from 13 to 20, 685; from 20 to 30, 1,586; from 30 to 40, 1,076; from 40 to 50, 435; from 50 to 60, 266; from 60 to 70, 161; from 70 to 80, 50; over 80 years of age, 5. It will, therefore, be seen that the vast majority of the cases are in persons from 20 to 40 years of age, very few below 10 years of age, and very few above 60 years of age. The occupation of the tuberculous individuals is also given. It states that there are 10 physicians who have tuberculosis. The report also gives the results that have been obtained by different methods of treatment in various parts of the world and ends with the following conclusions: 1. There are at least 7,000, probably 7,500 cases of tuberculosis in Iowa; 2, that the best means of preventing the spread of the disease is by informing the people regarding the dangers of tuberculosis, the reporting of all cases, prohibiting expectoration in public places, and the removal of consumptives to sanatoria.

KANSAS.

New Hospital.—A new hospital is to be erected at Independence to contain 25 rooms and to cost about \$10,000.

Orders Fumigation of Street Cars.—The city board of health of Topeka has issued an order requiring the Topeka Railway to fumigate its street cars at least once a month.

Diphtheria Prevalent.—During the month of February there were 220 cases of diphtheria and 29 deaths, as compared with 55 cases and 10 deaths for the corresponding period of 1905.

Smallpox.—Four cases of smallpox have developed among the convicts from Kansas and Oklahoma confined in the state penitentiary at Lansing. The prison has been placed under strict quarantine; no convicts will be received or discharged, and no guards will be permitted to leave the prison until the quarantine is raised. More than 1,000 of the convicts have been vaccinated.

MARYLAND.

Baltimore.

Health Report.—Five cases of smallpox were reported during the week ended March 17. Diseases due to cold and wet were in the majority. The deaths from pneumonia were 37; from consumption, 32; from bronchitis, 7; from influenza and whooping cough, each 5.

Personal.—Among those who will go abroad this summer are Drs. Randolph Winslow, J. Mason Hundley and Frederick Bohyns.—Dr. Ira Remsen, president of the Johns Hopkins University, is in California this week, attending a meeting of the American Universities, held under the joint auspices of Leland Stanford and California universities at San Francisco, March 11 to 17.—Dr. Thomas S. Cullen sailed on March 14 for a trip of several months through Europe.—Dr. William A. Parvis is recuperating his health at Mount Jackson, Va., and will leave for Colorado June 15.—Dr. Sumnerfield B. Bond has been appointed chief medical examiner of the Baltimore & Ohio Railroad.—Dr. Harry D. Purdum has resigned from the resident staff of the University Hospital to accept a position in a Michigan insane hospital.

Tuberculosis Bills.—There are now two bills before the legislature for a tuberculosis sanitarium, one asking an appropriation of \$100,000, the other of \$25,000. The former contemplates a state institution, the latter simply an appendage to the present Endowed Consumptive Hospital. It is claimed by

advocates of the second bill that contributions can hereafter only be secured for the proposed institution by its remaining private, and that, in fact, a large amount has already been secured. The state bill, however, has the backing of the profession and was urged at Annapolis, March 13, by Drs. Welch, Thayer, Finney, Fulton, Hocking and others. While advocating the state institution these gentlemen, however, are not opposed to the appropriation also asked for the Endowed institution, over which Dr. Henry Barton Jacobs presides and in which he is specially interested.

MISSOURI.

Hospital Opened.—The Sisters of Mercy at Springfield, Mo., opened to the public an February 22 the new St. John's Hospital, recently erected at a cost of \$50,000.

Accident.—Dr. R. Wood Brown, Kansas City, sustained a fracture of the left leg in a fall from a street car, January 24, and lay in the street for more than four hours before help was rendered him.

St. Louis Urological Society.—This society was organized March 16 with twelve charter members. Dr. Bransford Lewis was elected president, and Dr. Eugene A. Scharff, secretary and treasurer.

Fined for Illegal Practice.—Dr. R. D. Haley, an advertising specialist, and his assistant, C. W. Laybourn, St. Louis, were each fined \$500 for practicing medicine without a license, February 28. They both gave notice of appeal.

Goes to Prison Unguarded.—Dr. Joseph D. Todd, Richards, was sentenced to imprisonment for twelve years for the murder of Robert Wall and appealed, being released on bail. When the decision of the lower court was affirmed by the Supreme Court, March 6, he went to the penitentiary and reported to the warden to begin serving his sentence.

Personal.—Drs. Augustus C. Bernays, George W. Cale, Jr., Willard Bartlett and John M. Dean have gone to Rochester, Minn., for a week.—Dr. and Mrs. Jefferson D. Griffith, Kansas City, sailed for Europe, February 8.—Dr. Charles M. Johnson, St. Charles, celebrated his eightieth birthday January 28, and his golden wedding anniversary on February 26.

NEW YORK.

The Epidemic at Yonkers.—The epidemic of tonsillitis in this city continues unabated and hundreds of people are confined to their homes.

Brooklyn's Water Supply.—Bills have been introduced into the legislature repealing the laws of last year prohibiting New York City from going to Long Island for a water supply, and giving Brooklyn permission to get water from Suffolk and Nassau counties.

Oppose Osteopathy Bill.—The State Department of Education has issued a formal statement to the members of the legislature declaring that, contrary to widely circulated reports, the department was opposed to the pending bill to secure legal recognition for the practice of osteopathy in the state. They assert that the state should not recognize any school of practice in medicine any more than any special creed or cult.

Personal.—Dr. F. Park Lewis, Buffalo, will spend the summer in Europe.—Dr. Roswell Park, Buffalo, has resumed his work after his severe illness.—Drs. Harvey Gaylord and G. Clowes of the New York State Cancer Laboratory, Buffalo, have sailed for Jamaica.—Dr. Burt C. Johnson, Buffalo, has gone to Europe.—Dr. William Mahon has been appointed superintendent of the Manhattan State Hospital, Ward's Island.

Osteopathic Legislation.—The osteopaths have again begun a campaign for medical license from the state. At a recent hearing at Albany Mr. M. W. Littleton spoke before the committee of the Assembly and the Senate. The medical profession was well represented in opposition to this bill. Last year the committee rejected the bill, and it is sincerely hoped that a similar fate awaits it this session.—Assemblyman Cox has introduced a new osteopathic bill which provides for a separate board of examiners and a three-year graded course.

Milk Decision Affirmed.—The validity of the law of the state prohibiting the vending of milk containing less than 12 per cent. of milk solids was argued before the Supreme Court of the United States in the case of Frederick S. John, a Buffalo milk dealer who was arrested for violating the law. The Supreme Court of New York affirmed his conviction and the constitutionality of the law, denying his plea that it deprived him of the equal protection of the law guaranteed by the federal Constitution. St. John's complaint was that the trial jus-

tice refused to allow him to prove that the milk he sold was in the same condition that it came from the cows and had not been adulterated, thus depriving him of the chance to prove his innocence.

Society Celebrates Centennial.—The Medical Society of the County of Rensselaer celebrated the one hundredth anniversary of its organization at Troy, February 22, with a banquet at which 125 members and guests were present. Dr. C. Howard Travell, the president, officiated as toastmaster, and addresses were made by Corporation Counsel George P. Wellington, who spoke on "Scientific Politics"; Dr. William M. Polk, New York City, who responded to the toast of "The Physician and the Layman"; County Judge Michael E. Tierney, who spoke of "The Physician in Law"; Prof. William D. Mason of the Rensselaer Polytechnic Institute, who responded to the toast "Professional Education," and Dr. R. Brockway, Bontecou, the Nestor of the society, who gave an exhaustive résumé of the growth and development of the organization.

Sea Side Hospital and Convalescent Home.—Assemblyman Tompkins has a bill before the legislature which creates a commission for the purchase of a stretch of ocean front on Long Island to be converted into a free park and convalescent home. This measure was first proposed by Mayor McClellan of New York in a message to the board of aldermen, in which he said: "Provision must soon be made by the city toward securing fresh air homes for children and convalescent patients from the city hospitals as well as breathing spaces for the whole people." It is proposed to set aside \$2,500,000 for this excellent project. Anticipating the passage of the bill sites have been discussed and suggested at Long Branch, Coney Island and Rockaway Beach. This building of hospitals and convalescent homes by the sea though apparently a modern idea is ancient, for in antiquity they built temples to Esculapius near the sea side, and many great and ancient institutions of medical renown were situated on the sea side. This is particularly true of the great school of Salerno, one of whose teachers, a woman, Tratulua, wrote a treatise on the value of sea baths.

New York City.

Ball for Hospital.—Beth Israel Hospital's annual Purim ball was held March 14, when \$10,000 was realized for this hospital.

Hospitals Crowded.—It has become necessary to set apart two wards of Bellevue Hospital for tuberculosis patients, as there is room for no more tuberculosis patients at Blackwell's Island. As a result of this action the medical wards of Bellevue are somewhat overcrowded.

Health Department After Fur Dealers.—Notices have been served on dealers in raw furs in the business district that they must ventilate their work rooms from the top or stop dealing in "green" furs. The department insists that they shall ventilate through the roofs and then apply for a permit to do business as the law requires.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended March 10, 2,384 cases of measles, with 55 deaths; 436 cases of diphtheria, with 62 deaths; 414 cases of tuberculosis, with 187 deaths; 250 cases of scarlet fever, with 13 deaths; 30 cases of cerebrospinal meningitis, with 25 deaths; 17 cases of typhoid fever, with 3 deaths, and 171 cases of varicella, making a total of 3,702 cases, with 345 deaths.

Street Cleaning and Pure Food.—A resolution for the issuance of special revenue bonds to the amount of \$25,000 for the special investigation of the street cleaning department was adopted at the last meeting of the board of aldermen. A resolution was also adopted urging the legislature to grant Dr. Darlington an appropriation for the investigation of the purity and healthfulness of foods, wines and beverages manufactured and sold in this state.

Concealed Measles.—Health inspectors in the Bronx have discovered that no less than 50 cases of measles in well-to-do families were not reported by the attending physician, and in cases where no physician was summoned mothers and nurses were charged with willful neglect. These cases were all located in the neighborhood of the Bedford Park school and have had such an effect on the attendance that the school may have to be closed. Several children attended school while affected with the disease, and the health department has ordered a thorough investigation.

Homes for Medical Students.—The woman's advisory board of the Students' Club, the intercollegiate branch of the Young Men's Christian Association, is endeavoring to enlarge the work that it is conducting for medical students. John H. McCracken stated that there were not as many medical students in New

York as there were twenty years ago, owing to the lack of accommodation, and that if there was one class of men neglected more than another it was the medical students. It was right that more attention should be given to the housing of medical students and efforts would be made to enlarge the home so that forty men could be accommodated. The board has \$2,000 toward furnishing the new home.

Transfer of Dying Patients.—The practice of transferring dying patients from one hospital to another for the purpose of keeping down death rates has been criticised from time to time, and several deaths that have occurred recently have brought this matter to the attention of the coroners, who have framed the following resolutions:

Resolved, That this is in violation of all principles of justice and humanity, and meets with our disapproval; that we not only object but protest and ask that all persons in charge of hospitals take measures at once and instruct the physicians in charge of patients not to remove them to other hospitals when conditions are such as to endanger the lives of the patients; and it is further *Resolved*, That if this matter is disregarded this board will take stringent measures to bring the violator to justice.

NORTH CAROLINA.

State Society Meeting.—The Medical Society of the State of North Carolina will hold its fifty-third annual session in Charlotte, May 29, 30 and 31. The State Board of Medical Examiners will meet in the same city May 24.

Hospital News.—Mercy General Hospital, Charlotte, was informally opened and dedicated February 26.—Two Philadelphia surgeons have purchased the old military school building at Rutherfordton and will erect a hospital and sanitarium to cost \$25,000.

January Deaths.—During January 222 deaths were reported, equivalent to an annual mortality of 17.1 per 1,000. Pneumonia caused 44 deaths, consumption, 23; heart disease, 16; brain diseases and diarrheal diseases, each 14; nervous diseases, 10, and accidents and violence, 9.

Personal.—Dr. James S. Lafferty, Concord, has removed to Greensboro.—Dr. Peter E. Hines, Raleigh, is critically ill with cerebral hemorrhage at his home.—Mrs. Ginnada T. Sykes, Grissom, and Erwin Q. R. Houston, Davidson, recently suffered severe losses by the burning of their residences.—Dr. Hubert A. Royster, Raleigh, has retired from general practice and now devotes himself exclusively to surgery and gynecology.—Dr. Richard H. Lewis, Raleigh, has been elected president, and Dr. Chase P. Ambler, Asheville, a member of the executive committee, of the Audubon Society of North Carolina.—Dr. McTyeire G. Anders, Connolly Springs, has located in Gastonia.

The Matthews Case.—Dr. Joseph B. Matthews, Greensboro, who was held after a preliminary hearing before a magistrate for trial at the next session of the Guilford Superior Court on the charge of having murdered his wife, was found guilty and sentenced to imprisonment for twenty years. The evidence was of a most serious nature. Three physicians who were called into the case found Mrs. Matthews in a dying condition from an excess of morphin, and it was with great difficulty and prolonged efforts they succeeded in reviving her. Constant efforts were made during the day by Dr. Matthews to get the physicians out of the room on various pretexts. Finally in the afternoon he succeeded, and returning after a short absence, two of the physicians discovered Dr. Matthews injecting a concentrated solution of strychnin into his wife's body. Her death ensued shortly after with the characteristic symptoms of strychnin poisoning.

NORTH DAKOTA.

Personal.—Dr. D. Tuffe, Fargo, has returned after six months in Europe.—Dr. J. Dempster Taylor, Minot, has been re-elected physician of Ward County.

New Hospitals.—The new hospital for the insane at Jamestown has just been completed at a cost of \$60,000.—The Lutheran Hospital Association has decided to erect a hospital at Rugby, to cost about \$30,000.

Births and Deaths of 1905. The secretary of the State Board of Health reports that during 1905, 4,912 births were reported to the board and only 1,747 deaths. Of the latter 479 were due to communicable diseases.

Agreement Regarding Insurance Examinations.—Physicians registered and practicing in the sixth councilor district, believing that the duties of insurance medical examiners require a high degree of professional skill, absolute integrity and special attention to the interests of the insurance companies, have pledged themselves to exercise skill and care in all examina-

tions and to make no discrimination in examinations or fees to different companies. They agree to be governed by the following schedule of fees: \$5 for each ordinary examination, including urinalysis; \$10 for each examination where microscopic examination of urine, sputum or other secretion is required, and \$3 for each certificate of health for renewal of lapsed policy. This agreement has been signed by all the physicians in Burlington and Kidder counties, and copies have been sent for signature to the physicians in the other counties in the sixth judicial district.

OHIO.

Hospital Needed.—Middletown is in urgent need of a hospital, and Dr. David B. Bundy has offered \$1,500 toward the establishment of such an institution.

Dr. Haugh Found Guilty.—Dr. Oliver C. Haugh, Dayton, charged with the murder of his father, mother and brother, was found guilty, March 9, of murder in the first degree.

Injured and Ill.—Dr. James W. Ward, Lytle, suffered a serious injury to one of his eyes a few days ago.—Dr. Addison K. Kirkpatrick, Eckmansville, has been taken to Cincinnati, where he will undergo a surgical operation.

Hospital Patients in Peril.—The Cleveland Homeopathic Medical College was practically destroyed by fire March 9, and the Huron Road Hospital, with its 63 patients, was placed in grave jeopardy thereby. Fortunately a panic was prevented, but one patient died from shock.

White Hospital Report.—The annual report of the White Hospital, Ravenna, for the year ended Jan. 1, 1906, shows that 182 surgical cases, 163 medical cases, and 23 obstetrical cases were received during the year. Six patients were moribund on admission and, including these, there were 13 deaths during the year.

A Frank Confession.—Health Officer Allen of Cincinnati has received the following naive letter from a delinquent dairyman: "I have investigated, and find that my night men, instead of putting filtered water into the milk, used hydrant water. You see, I have been putting one gallon of water into every can of milk because the cows give so little milk now and it is so rich."

Personal.—Dr. William S. Bond, Hubbard, is recovering from an attack of pneumonia.—Dr. Daniel A. Berndt, Portsmouth, has been appointed assistant surgeon of the Norfolk & Western Railway.—Dr. Harry R. Geyer has been appointed workhouse physician of Zanesville, vice Dr. Herbert J. Sheppard, resigned.—Dr. Harrie B. Martin, Springfield, has returned after two years abroad.—Dr. Rufus D. Jacobs, Vinton, who has been seriously ill, is improving.

PENNSYLVANIA.

Smallpox at Bethlehem.—A case of smallpox was reported in South Bethlehem, March 11. The victim was a Russian immigrant, who landed in New York twelve days before. It is stated that she was allowed to land by the United States quarantine officials in New York, although she had no marks indicating previous vaccination.

Free Hospital for Poor Consumptives.—The report of the Free Hospital for Consumptives, White Haven, for the year ended March 1, shows that 540 patients were treated in the institution. There were but 2 deaths, one of these an employe of the institution and the other a female patient about to be discharged, both deaths being due to pneumonia. There were 114 patients in the sanatorium March 1, 1905, and 426 patients were admitted during the year. The patients discharged during the year numbered 268, while those leaving numbered 134. On February 28, 133 persons remained at the sanatorium. Of the total number of patients treated the report states that in 142 the disease was arrested; in 85 the condition was greatly improved; 83 were reported improved, and 76 not improved. During the year 165,820 quarts of milk were used, and 281,766 eggs, at a cost of \$7,192.64 for milk and \$5,765.51 for eggs. The receipts for the year were \$73,587.03, and expenditures, \$73,585.72.

Philadelphia.

Announcement.—At the March 28 meeting of the Philadelphia County Medical Society a symposium on sanitary and moral prophylaxis will be held, and the educational movement for the prevention of venereal disease will be fully considered. The meeting will be addressed by Dr. Prince A. Morrow of New York City.

Smallpox Appears.—One case of smallpox was reported during the week in a colored child. This is the first case of this

disease reported for fifteen months, and every effort is being made by the authorities to prevent the spread of the disease. All the houses in the immediate neighborhood were quarantined and fumigated.

Personal.—Dr. George W. McCafferty has been appointed to succeed the late Dr. David D. Richardson as resident physician of the State Hospital for the Insane, Norristown.—Dr. Clarence A. Veasey has returned from a visit to southern California.—The report that Dr. J. C. McCracken, who represents the University of Pennsylvania in China, was injured in the recent riots, is unfounded.

Examinations for Internships.—The following hospitals have announced the dates of their examinations for resident physicians: St. Joseph's Hospital, Philadelphia, May 1, six vacancies to be filled; term of service, sixteen months. Methodist Episcopal Hospital, Philadelphia, April 12, and Allegheny General Hospital, simultaneously in Philadelphia, Pittsburgh and Ann Arbor, Mich., April 7, at 9 a. m.

Addresses.—Dr. Richard Hunt, Washington, D. C., addressed the Pathological Society of Philadelphia, March 22, on "Studies in Metabolism in Relation to Alcoholism."—Dr. Casey A. Wood, Chicago, addressed the section on ophthalmology at the College of Physicians, March 20, on "Some Forms of Hereditary Cataract."—Dr. Philip P. Calvert addressed the Fortnightly Club of Mount Holly, N. J., March 12, on "Historical Sketch of the Discovery of the Deep Sea Animals."

Medical Staff of Widener Memorial.—The medical staff of the Widener Memorial Home for Crippled Children, which was formally opened March 3, will be composed of the following men: Surgeon-in-charge Dr. DeForest Willard; assistant surgeon, Dr. Edward B. Hodge, Jr.; visiting physician, Dr. Albert D. Ferguson; pediatric, Dr. Alfred Hand, Jr.; neurologist, Dr. William G. Spiller; ophthalmologist, Dr. G. Oram Ring; assistant ophthalmologist, Dr. Carl S. Williams; laryngologist, Dr. Francis R. Packard; dermatologist, Dr. Jay F. Schamberg, and pathologist, Dr. Robert L. Pitfield.

Medical Visits to Schools.—The report of the work of the assistant medical inspectors in the bureau of health during February shows that 5,985 visits were made to the public schools, in which 19,818 pupils were examined. There were 1,064 pupils excluded from school on account of illness, 553 of whom were girls and 511 boys. Of the number excluded 245 were suffering from measles and 118 from measles contact; 16 from diphtheria and 9 from diphtheria contact; 6 from scarlet fever and 6 from scarlet fever contact; 42 from chickenpox; 35 from acute conjunctivitis; 32 from ringworm; 100 from mumps, and 2 from erysipelas. The inspectors performed 121 vaccinations and, in addition, reported 3,443 children to their parents as being in need of medical attention.

Health Report.—The total number of deaths reported for the week reached 591, as compared with 633 reported last week, and 589 reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 26; measles, 19; scarlet fever, 3; whooping cough, 4; diphtheria, 16; meningitis, 2; consumption, 70; cancer, 25; apoplexy, 20; heart disease, 54; acute respiratory disease, 96; enteritis, 34; appendicitis, 5; Bright's disease, 43; puerperal sepsis, 5; suicide, 5; accidents, 16, and marasmus, 4. There were 448 cases of contagious disease reported, with 48 deaths, as compared with 357 cases and 46 deaths in the previous week. The number of contagious disease cases reported shows, therefore, a large increase over the previous week, particularly in diphtheria and typhoid fever, 117 cases of the former and 287 of the latter being reported, as compared with 77 cases of diphtheria and 231 cases of typhoid in the previous week.

Money for Charity.—At the meeting of the executive committee of the twenty-sixth annual charity ball the treasurer was authorized to distribute \$2,350 to each of the following beneficiaries: Hospital of the University of Pennsylvania, Jefferson Medical College Hospital, Howard Hospital and St. Timothy's Hospital.—By the will of the late Edward T. Dobbins the following institutions are named as beneficiaries: Women's Medical College Hospital, to endow a free bed, \$3,000; Women's Medical College, to pay tuition for the regular course of instruction in medicine of a young woman who can pass the necessary examination, preference being given to a graduate trained nurse, \$3,000; Burlington County Hospital, \$5,000; Philadelphia Home for Incurables, \$5,000; to maintain a scholarship at the Philadelphia College of Pharmacy, to be conferred on a New Jersey apprentice passing the highest preliminary examination, \$2,500; Christ Church Hospital, \$10,000, and Hospital of the Women's Medical College,

\$10,000.—As a result of an autograph auction book sale held at the Germantown Cricket Club \$800 was realized, which is to be donated to the Germantown Hospital.

GENERAL.

Gastro-Enterologists to Meet at Boston.—The ninth annual meeting of the American Gastro-Enterological Association will be held at Boston, June 4 and 5, 1906. The president's address, "The Mutual Obligations of the Surgeons and Internists in the Proper Development of Gastric Surgery," will be by Dr. H. W. Bettmann, Cincinnati.

Prevention of Yellow Fever.—In response to the request of a number of citizens of New Orleans, six surgeons of the Public Health and Marine-Hospital Service have been assigned to visit the parishes adjacent to that city to assist the state authorities in such measures as may be necessary to prevent a recurrence of yellow fever during the coming summer.

Cholera in the Philippines.—Dr. Heiser, chief quarantine officer at Manila, states in *Public Health Reports* that there is a gradual increase in the number of cases of cholera reported from the provinces. Many cases of the disease are occurring among the fishermen and others who are employed on the small craft which ply between the upper end of Manila Bay and the numerous rivers which lead into it from Bulacan and Pampanga provinces. The infected territory is lowland and marshy. The villages are built along the banks of the rivers on unsanitary sites. If there is any considerable increase in the number of cases, the direct drainage into the rivers will no doubt soon infect them and then a more serious epidemic is to be expected. The eradication of the disease will be exceedingly difficult, and under the most favorable circumstances a number of months will probably elapse before the disease can be checked in these provinces.

Quarantine Regulations for Fruit Vessels.—Strict regulations are to be enforced regarding fruit vessels at foreign ports suspected of being infected with yellow fever. The captain or his representative is to be the only person allowed to land, and that only to enter and to clear the vessel, and then only in the daytime. No one from the shore is to be allowed to board the vessel, except customs officers and the agent of the ship. Fruit intended for shipment on vessels lying at docks is to be graded and payment made for it on shore or at the dock. Passengers must embark at the regular ports and must have been under observation by a United States sanitary inspector for at least five days prior to the departure of the ship. The vessel must not lie where the crew will be exposed to the danger of contracting yellow fever, and at ports where the vessels lie at wharves the vessel must be moved into the stream or at least 200 meters from the wharf before sunset, and not returned to the wharf before sunrise the following day, except at ports where previous permission has been obtained. Water tanks, water buckets and other collections of water about the vessels are to be guarded in such manner that they shall not become breeding places for mosquitoes. The destruction of mosquitoes aboard must be insured as far as possible by the simultaneous fumigation—two pounds of sulphur per 1,000 cubic feet, all openings closed for two hours—of all compartments which can be so treated without injury to the cargo. Pyrethrum powder may be substituted in the engine room at the option of the medical officer. The vessel is to sail immediately after this fumigation is completed. All baggage is to be rigidly inspected and the exclusion of mosquitoes assured. Fruit vessels plying between United States ports and fruit ports where yellow fever is known to exist will not be admitted to entry under the provisions of these special regulations until they have been not less than five days from the port of departure before being admitted to pratique at the quarantine station at the port of arrival. Fruit vessels without certificates of the United States sanitary inspectors at foreign ports and fruit vessels infected with yellow fever will be subject to the general quarantine regulations of the United States. Persons exposed to infection in unloading cargoes on to lighters shall be detained after such exposure, as provided for other persons exposed to yellow fever. Any officer of a fruit vessel detected in evading or violating these special regulations shall forfeit, for any vessel on which he may subsequently be found, or be engaged, any participation in the special privileges accorded by these regulations. Fruit vessels trading with any ports infected with yellow fever must carry a competent, qualified physician. Fruit vessels arriving with yellow fever on board, or having had yellow fever on board during the voyage will be quarantined. The personnel shall be removed, with the exception of the master, the living apartments thoroughly disinfected, the ves-

sel provided with a new crew, sufficient to care for her, and towed to the docks for the discharge of cargo. On completion of the discharge of cargo the holds are to be fumigated with sulphur and the vessel towed to the quarantine station to take on her crew before proceeding to sea.

FOREIGN.

Immunity of Lime Workers to Tuberculosis. We are informed that a communication signed by more than a thousand physicians is to be presented at the approaching International Medical Congress on the subject of "Immunity to Tuberculosis of Workers in Lime and Gypsum Kilns." The *Siglo Medico* publishes an appeal for all physicians who have any experience in the matter to inform those getting up the article. Address Dr. G. Fisac, provincia de Ciudad Real, Duiniel, Spain.

Moritz Steinschneider.—The international journal devoted to the history of medicine and medical geography, *Janus*, in its issue for February, pays homage to the oriental student, Moritz Steinschneider, who reached the age of 90 March 30, 1906. He is still actively engaged as occasional assistant at the Berlin Royal Library. His researches on the pharmacology, toxicology, medicine and natural sciences of the Arabian and other writers during and just preceding the Middle Ages will be a mine of information for generations of scientists yet unborn.

Smallpox in India.—The epidemic of smallpox which began in Calcutta in December shows no signs of abatement. It is impossible to determine accurately the number of cases or deaths, as they are rarely reported to the health department. Hindoos of all classes are averse to hospital treatment of every kind, and they dislike to have any disinfecting operations carried on in their houses. They also look on smallpox as a very ordinary visitation. Because of these facts they not only do not report cases, but conceal them. It is estimated that there have been about 5,500 cases since December.

Medical Boycott in Italy.—Under the heading "Boicottaggio del Comune di Lentini," the *Gazz. degli Ospedali* for March 1 publishes an appeal from the president of the National Association of District Physicians. He calls on the presidents of the various local medical associations and the members to stand by Dr. L. Piazza, until recently district physician in the commune of Lentini. He has always conducted himself with honor and professional devotion, and his abrupt dismissal by the local authorities was an undeserved insult. The commune is now without a district physician, and it is proposed to boycott it until Dr. Piazza is restored to his position or reparation offered.

Recrudescence of Plague in Brazil.—Recently 11 fatal cases of plague have been reported in Bahia. The number of other cases is not stated. The outbreak appears to be a recrudescence and not new cases introduced from Rio de Janeiro or other Brazilian ports. During the week ending January 21, 2 deaths from bubonic plague were reported in the city of São Paulo. These cases appear to have occurred in individuals arriving there from other ports; one of these patients had lately been in the city of Rio. During the last three years sporadic cases have from time to time made their appearance in that city, but there has never been anything pointing to any infection of the city itself.

Medical Institutions Founded as Anniversary Presents.—As already mentioned, the emperor and empress of Germany announced some time ago that on the occasion of their silver wedding they would prefer not to have personal gifts made to them, but rather to have the occasion celebrated by endowments of charitable and medical institutions. Thirty cities have announced their intention of founding various institutions, representing a total expenditure of more than \$600,000. The list includes homes for convalescents, for infants, means to reduce infant mortality, hospitals for the blind asylums, sanatoria, etc. Several of the institutions are to be endowed by private individuals. Berlin has appropriated funds for a sanatorium for lung affections, for the model infant asylum, for a maternity, and for a "night nursery." The largest amount was given by Breslau \$90,000 to found an infant asylum.

New Journal of Applied Hygiene. The first number of a new French monthly, *L'Hygiène Générale et Appliquée*, has been received. It has been founded by Chantemesse, professor of hygiene at Paris, chief of the national sanitary service. Its aim is to popularize hygienic measures and record their successful application. The first number opens with a sketch by Chantemesse of the late epidemic of yellow fever in New Orleans, and the lessons to be learned therefrom. The second

article describes the workings of the course in hygiene, entitling to a diploma, recently organized at Lyons. Forty-nine persons are taking the course, including a number of pharmacists, architects, chemists, and teachers, as well as physicians and medical students. Requests have already been received for an evening course of lectures for persons employed during the day. Other articles are on the "House Book," and other topics connected with hygiene. The editors urge the readers to send in reports of successful stamping out of epidemics or of eradication of insanitary conditions, and to ask questions on any subject in the line of sanitation or hygiene. Replies by experts will be published in the monthly. 1. is issued by O. Doin, Place de l'Odéon, Paris. The subscription is 12 francs, or about \$2.40, including postage.

German Sleeping Sickness Commission to Africa.—The German government has appropriated about \$30,000 for the expenses of a scientific commission to study sleeping sickness in Africa. Robert Koch is to head the party, which will include Drs. Beck and Kleine, his assistants on his former trips. His wife will accompany him as usual. The party sails from Naples April 16, and expects to be gone a year and a half. In an address delivered recently in Berlin Koch described the history and onward march of sleeping sickness in Africa, where it has been known since the beginning of the last century. At first confined to the west coast, it has now spread to the north shore of Lake Victoria Nyanza, and is threatening the German possessions. He remarked that nearly a quarter of a million people had probably died from the disease, whole villages having been thus depopulated; on certain islands he found that the inhabitants had died to the last person. No remedy is known for the disease; the main hope is to exterminate the insect in which the germ breeds. This might possibly be accomplished, he said, by burning the undergrowth in its haunts. It is only a few months since Koch returned from a scientific trip to Eastern Africa, bringing back several new data in regard to trypanosoma infection and other tropical affections, as was mentioned in these columns on page 1888 of the last volume. His illustrated communication on the subject was published in the *Deutsche Med. Wochts.* for Nov. 23, 1905, page 1865. A brief summary was given in these columns on page 236 of the current volume.

Official Postgraduate Instruction in Germany.—An imposing four-story building was dedicated in Berlin on March 1, which is unique in its design, its construction and its purposes. It owes its inception to the late Empress Frederick, who from her deathbed impressed on the authorities the importance of up-to-date training for practicing physicians. Within a year twenty-four local centers had been formed for postgraduate instruction, and more than a third of all the physicians of the realm had taken advantage of the courses offered. The importance of the mechanical arts for the development of medicine was being recognized more and more. The perfected microscope, the Roentgen equipment, etc., required technical skill of the physician in which he had not been trained. To meet these wants and centralize and economize efforts in this line, the building known as the "Kaiserin Friedrich Haus" has been erected by popular subscription, costing about \$400,000. The first floor is devoted to the permanent exhibition of medical and surgical instruments and appliances, medical electricity, optics and medical chemistry. On the next floor is a reading room, an assembly hall and a permanent exhibition of trivial medicine, models and other plastic reproductions for teaching purposes and more exhibits of optical and mechanical devices. The floor above is devoted to the exhibits which are to be loaned out to other postgraduate centers, traveling exhibitions. The upper floor contains lecture rooms and laboratories for clinical chemistry and microscopy, bacteriology and experimental therapy, and for Roentgen work and scientific photography in general. The reading room is to contain the medical journals of the world and a small collection of the latest manuals, atlases and illustrated compendiums. The assembly hall has 200 seats, with standing room for 40. Each seat has a small writing-table attachment, and the blackboards and tablets on the wall are arranged so that they can be raised or lowered instantaneously, leaving the calcimined wall free for the lantern views. The loan exhibits are not arranged for museum purposes, but any or all of the objects in them can be loaned to physicians, teachers, lecturers, etc., for instruction of the general public or special classes, as well as to physicians. Various persons, especially physicians, have donated the funds to equip certain parts of the establishment in which they are most interested. The funds contributed have not all been expended and remain as a permanent endowment. The state also aids in the support of the institution. The *Zeitschrift f. ärztliche*

Fortbildung, of which Dr. R. Kutner is editor, is the official organ of the "Äerztliche Fortbildungswesen," as the entire postgraduate movement is called. Its editorial office has been removed to the new building, Berlin NW, 6, Lusenplatz 2-4. The issue for March 1 contains an illustrated description of the ceremonies attending the opening of the house, as part of the silver wedding celebration for the royal pair, with a view of the building and diagrams of the various floors. Sir Felix Semon represented Great Britain at the ceremonies, Blondel, France, and von Gross, Hungary.

LONDON LETTER.

The Duration of the Medical Curriculum.

An important report on the duration of the medical curriculum has been presented to the Royal College of Physicians by the Committee of Management of the Conjoint Examining Board in England, consisting of Dr. F. Taylor, chairman, Dr. Norman Moore, Dr. E. Living, Mr. J. Langton, Mr. E. Owen and Mr. R. J. Godlee. In 1890, the duration of the medical curriculum was extended from four to five years. It was hoped that the additional years would lead to more thorough study of practical subjects before the final examination. In the opinion of most teachers, however, this result has not been attained, for, owing to the greater demands on the student's time by the accessory scientific subjects, less time is devoted to practical subjects than formerly. It has been suggested that another year be added to the curriculum or that the student be required to pass the preliminary scientific examination in chemistry, physics and biology before commencing his five years' education at a medical school. The latter proposal, at the instance of the council of the Royal College of Surgeons, was referred to the committee of management of the conjoint board. The committee thought it desirable to ascertain the present length of the curriculum and how long it takes the average student to pass all his examinations. Analysis of the records of 400 students who obtained the diplomas of the conjoint board during the last two years shows that only 8.5 per cent. passed the final examination in five years and only 28 per cent. in less than six years; 71.5 per cent. took six years or more to pass and 34.5 per cent. took more than seven years. These figures are derived from a period when the regulations adopted by the Royal Colleges in June, 1904, had not come fully into operation. It is not improbable that under these new regulations a year may be added to the total period of study required before the final examinations. Probably the student will take from five and one-half to seven years in his medical education. This is a serious prospect for parents, and suggests that the present system is too much for the capacity of students. The committee of management of the conjoint board is of opinion, however, that any alteration in the present regulations is undesirable.

The Liverpool School of Tropical Medicine.

The report of the Liverpool School of Tropical Medicine again shows a record of much good work accomplished by this enterprising institution. A special research on trypanosomiasis was carried on in connection with the Congo expedition. This school has an advantage over the services of one staffs of the allied sciences, who are also working along this line in the Johnston laboratories, viz., the comparative pathology department, the veterinary school of the University of Liverpool, the bio-chemistry department and others. The Johnston laboratories of the University of Liverpool, where accommodation for the research work and teaching of the school is provided, were presented to the university by Mr. William Johnston. The buildings are on the east side of the celebrated Thompson-Yates laboratories which they adjoin. They are 90 feet long and 47 feet wide at their broadest part, and 34 feet wide at their narrowest. They contain four floors (connected by staircases and by an elevator), each devoted to separate departments of study and research, and under the control of various professors and lecturers. The basement is devoted to comparative pathology and is under the control of Dr. Annett. The ground floor is devoted to tropical medicine and is controlled by Professor Ross. The first floor is devoted to the study of experimental medicine, including experimental investigation in medicine, pathology, physiology, bacteriology and allied subjects, under the superintendence of the professors of physiology and pathology. One set of rooms is devoted exclusively to cancer research under the direction of Mr. J. E. S. Moore. The second floor is assigned to bio-chemistry, and is presided over by Prof. Benjamin Moore. The laboratories of tropical medicine occupy a room about

95 feet long and 35 feet broad. The main part of the room is devoted to students, but three chambers are partitioned off for the special use of individuals who wish to do research work in connection with tropical medicine and parasitology. There is accommodation for forty workers. The partitions of the room are fitted with cupboards, in which the museum of tropical diseases, which the school is now forming, is being arranged.

A Comparison of Fresh and Concentrated Infusions.

In order to determine whether concentrated infusions of drugs are, from a pharmaceutical standpoint as good as fresh infusions, Mr. E. H. Farr and Mr. R. Wright, examiners to the Pharmaceutical Society, prepared a series of official infusions and of corresponding concentrated infusions for purposes of comparison. Though they had a predilection for fresh infusions, they found that in the majority of cases the concentrated infusions were quite as representative of the drug. The concentrated infusions of broom, cloves, orange, and, to a less extent, buchu and roses, were inferior to fresh infusions. On the other hand, concentrated infusions of senna and valerian were superior to fresh infusions. In the case of buchu there is the difficulty that the drug contains volatile oil and mucilage, both of which are therapeutically valuable. An alcoholic preparation does not dissolve the mucilage; on the other hand, a certain amount of volatile oil accompanies the mucilage into solution in an aqueous infusion. It is satisfactory to know that concentrated infusions in general fully represent the drugs from which they are prepared; but as in many cases they can be prepared only by the use of alcohol, they can not be considered therapeutically as equivalent to fresh infusions.

The King's Sanatorium.

The King Edward VII Sanatorium for Consumption, probably the best-equipped institution of its kind in the world, has just been completed, fifteen months after the laying of the foundation stone. It is situated at Midhurst, Sussex, on the South Downs, and has cost \$1,000,000. The architect, Mr. Percy Adams, worked in co-operation with Dr. Latham in designing the institution and visited various continental sanatoria. The situation is an ideal one. The sanatorium is 600 feet above the level of the sea, which is twelve miles away. To the north it is sheltered by pine woods. The grounds exceed 150 acres and around the building have been laid out as terrace gardens. The rooms are so constructed as to collect all the light possible and to afford no lodgment for dust. There is accommodation for 100 patients. The corridors are protected half-way up by spring doors at regular intervals, so as to allow of free ventilation but of no through draft. Each bedroom allows of 1,730 cubic feet of air per head. On each floor is a wide outside balcony facing the south for promenaders. All the walls have a sanitary surface, which is like porcelain but is not so cold as glazed tiling would be.

The Metropolitan Asylums Board.

The Metropolitan Asylums Board is one of the most remarkable institutions of its kind in the world. It controls all the fever hospitals of London as well as other institutions. The scope of the work embraces an area of twenty-one square miles and a population of 4,648,950. Among the institutions controlled by it are fifteen hospitals for infectious diseases, six lunatic asylums and a land ambulance service with eight stations and 171 ambulance vehicles; a river ambulance service possessing three wharfs and five steamboats; the training ship *Exmouth* with infirmary on shore; a "shipping home" with accommodations for 60 boys; six homes for defective children; three seaside children's and seven other homes for children. In all, the board is responsible for forty-nine homes and hospitals. There are two recent additions—a home for convalescent fever patients and an asylum for imbeciles. The general expenditure for the year amounts to over \$5,000,000. Over 5,000 persons are employed on the staffs of the institutions, and there are 7,000 inmates of the asylums and 8,000 patients at the hospitals.

The After-Care Association.

A useful institution exists in London, known as the "After-Care Association," the object of which is to help poor persons discharged from asylums for the insane. The annual meeting was held under the presidency of Sir Richard Douglas Powell. The report stated that the work of the association during the past year had been very encouraging. There were 288 cases before the council—176 women and 112 men. The number successfully helped was greater than in any previous year. The total receipts in 1905 were \$5,000. The object of the association, the only one of its kind in the United Kingdom, is to enable people who had been in asylums to take up a useful part in life. This is done

by grants in aid, by influencing the friends of the patients on their behalf, by providing cottage homes and by educating public opinion on a matter to which as yet little thought is given. The occupations open to these poor people are necessarily somewhat restricted, but they might be usefully engaged in horticultural and agricultural pursuits of a simple kind and in simple handicrafts.

The Medical Profession in 1906.

The number of physicians on the Medical Registrar in 1906 is 38,921, an increase of 545 on the number of 1905. The number on the London list is 6,438, against 6,397 in 1905; the provincial list for England gives 16,976 against 16,718 in 1905. In the overcrowded state of the profession it is satisfactory that the rate of increase of the profession has been diminishing in recent years and, according to the most recent statistics, appears to be less than the increase of the population. The population of England and Wales, according to the census of 1901, was 32,527,843. In the middle of 1905 the estimated population was 34,152,977, an increase of a little over 5 per cent. The increase in the number of physicians in the same period was 921, a little under 4 per cent. In London the rate of increase is considerably less than the rest of England, amounting to 2.3 per cent.

Action for Injuries Due to Treatment by the X-Rays.

A most interesting action has been tried in the courts for damages due to alleged negligent treatment with the x-rays. The defendants were a firm of chemists who were in the habit of administering the x-rays. The plaintiff was a solicitor's clerk who was suffering from locomotor ataxia and was gradually losing power in his legs. The use of the x-rays was advised by a physician, who sent the patient to these chemists, who were in the habit of administering the x-rays for him. The plaintiff alleged that his feet were placed so close to the bulb that it touched the soles and that they were deeply burned. For the defense expert evidence was given showing that it was impossible for the plaintiff to have received the injuries alleged. There were no burns on the abdomen or other parts of the body to which the rays were applied.

Identification by Teeth.

A remarkable case of identification by teeth has just occurred. Two colliers were charged with breaking into a store and stealing. It was found that some one had bitten a piece off the side of a cheese and left the marks of his teeth. Suspicion falling on the two men they were arrested, and one of them unwillingly allowed a cast of his mouth to be made, which was found exactly to fit the marks on the cheese. Expert evidence was given by a dentist, who stated that no two sets of teeth are identical. The prisoner showed much anxiety that his mouth should be examined to see if his teeth would fit the impression on the cheese, and when this was done it was found that since his arrest he had knocked out a stump. He was found guilty.

The Death Rate.

The quarterly return of the registrar general shows that the death rate in England and Wales during 1905 fell to 15.2 per 1,000, which was lower than in any previous year since the civil registration was established nearly seventy years ago. The death rate has been below 17 per 1,000 in each year of the present century, and during the quinquennium, 1901-5, the mean annual death rate has been but 16 per 1,000—a decrease of 1.7 on the rates of the preceding quinquennial periods. Since the period 1861-5 there has been a steady decline of the death rate from 22.4 to 17.7 in 1896-1900.

Death Under Chlorid of Ethyl in a Dentist's Chair.

The dangers of the recently introduced general anesthetic chlorid of ethyl are illustrated by the following case: A clergyman, aged 67, went to a dentist to have four teeth extracted. Chlorid of ethyl was administered to him by a physician, the brother of the dentist. An average quantity of the anesthetic (5 c.c.) is said to have been given, but whether or not exclusion of air was practiced is not stated in the report. When the fourth tooth was drawn the patient became very pale and died almost immediately.

New Departure in the Prevention and Treatment of Tuberculosis.

At the Brompton Hospital for Consumption, a scheme is about to be introduced by which the benefits and educative influence can be extended to others than those who apply for treatment. It is proposed to get in touch with all the housemates of any phthisical patient who presents himself, ascertain their condition, treat them if necessary, and in any

case arrange that they are taught to keep themselves free from infection.

The Birmingham Anti-Corset League.

Birmingham possesses a society which is devoted to persuading women that they are seriously injuring themselves by wearing corsets. The members of the society are enthusiastic and demonstrate their views whenever possible. In a little over two years they have increased their numbers to 90, two-thirds of whom are women. They claim that there is an increasing demand for reformed dress outfits.

Epidemic of Cerebrospinal Meningitis.

Surgeon-General Fliin has issued a report to the local government board for Ireland on a localized epidemic of cerebrospinal meningitis which occurred in Innishoblin Island and in the Cloggan district of Ireland, neighboring areas separated by ten miles of sea. The origin of the epidemic could not be traced. No cases of epidemic meningitis have been reported in Ireland since 1900.

Pharmacology

Report of the Council on Pharmacy and Chemistry.

The following report was presented to the Board of Trustees of the American Medical Association at its meeting held Feb. 2-3, 1906:

To the Board of Trustees of the American Medical Association, Gentlemen:—We beg to make the following report:

A conference of the Council on Pharmacy and Chemistry was held at Cleveland, Sept. 11-12, 1905, to which certain manufacturing pharmaceutical and chemical houses were invited to send representatives, as the Council desired suggestions and criticisms regarding the general plan of the work. Several physicians were also invited. The rules were thoroughly considered and finally adopted in the revised form as follows:

(The term "article" shall mean any drug, chemical or similar preparation used in the treatment of disease.)

RULE 1.—No article will be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article be furnished for publication. The general composition of the vehicle, its alcoholic percentage, if any, and the identity of other preservatives, if present, must be furnished.

RULE 2.—No chemical compound will be admitted unless sufficient information be furnished regarding tests for identity, purity and strength, the rational formula or the structural formula, if known.

RULE 3.—No article that is advertised to the public will be admitted; but this rule will not apply to disinfectants and food preparations, except when advertised in an objectionable manner.

RULE 4.—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is indicated. (The therapeutic indications, properties and doses may be stated. (This rule does not apply to literature distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)

RULE 5.—No article will be admitted or retained concerning which the manufacturer, or his agents, make false or misleading statements as to geographical source, raw material from which made, or method of collection or preparation.

RULE 6.—No article will be admitted or retained of which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to therapeutic value.

RULE 7.—Labels on articles containing "poisonous" or "potent" substances must show the amounts of each of such ingredients in a given quantity of the product. A list of such substances will be prepared.

RULE 8.—If the trade name of an article is not sufficiently descriptive of its chemical composition or pharmaceutical character, or is, for any other reason, objectionable, the Council reserves the right to include with the trade name a descriptive title in the proposed book. Articles bearing objectionably suggestive names will be refused consideration.

RULE 9.—If the name of an article is registered, or the label copyrighted, the date of registration and a copy of the protected label should be furnished the Council. In case of registration in foreign countries, the name under which the article is registered should be supplied.

RULE 10.—If the article is patented—either process or product—the number and date of such patent or patents should be furnished.

The proposed book, "New and Non-Official Remedies," was also discussed, and it was tentatively agreed that it should be divided into two parts: Part I to consist of definite chemical compounds and simple pharmaceutical preparations, and Part II to comprise pharmaceutical mixtures. The plan of procedure referred to in the previous report was slightly elaborated. Since the conference the Council has considered the merits of various proprietary articles and has provisionally arranged and classified a large number of preparations which are considered worthy of recognition.

As indicated in the first report, the consideration of pharmaceutical mixtures—the vast majority of preparations belong to this class—proved a most difficult problem. Such a preparation is usually an ordinary mixture, made according to some physician's prescription, or after some well-known formula, modified in some way to disguise its identity, which has been placed on the market as a new preparation under a catchy or suggestive name, accompanied with extravagant therapeutic claims. Such preparations represent nothing new and involve no unusual skill in their manufacture. Their use is to be deplored, but if they are to be used a complete statement regarding their composition should be furnished to physicians. If this were done, and if all mystery regarding them were removed, their use would be very limited. It has been decided, however, that as many of these mixtures as conform to the rules will be placed in Part II of the proposed Annual, where, when similar, they will be grouped together and explicit reference be made to corresponding official preparations.

In this connection, however, it should be borne in mind that standard preparations, such as those in the Pharmacopoeia and in the National Formulary—fully equal, if not superior, to the proprietary mixtures—are not only listed in the catalogues of the manufacturing pharmacists and chemists, but are also easily compounded by any experienced retail pharmacist.

While the Council is acting solely for the medical profession it has remembered that there is no antagonism between legitimate pharmacy and medicine, that there is a mutual dependence, and that, consequently, there should be a mutual co-operation between the Council and legitimate pharmacists and chemists. While most of the well-known firms have been co-operating with the Council, some seem to hesitate about doing so. The Council believes, however, that this hesitation comes from the fact that these firms have not fully appreciated the objects for which it is working, and which are believed to be as much in the interest of scientific pharmacy as in the interest of scientific medicine, and therefore, in the interest of all honest and legitimate manufacturers. The Council has endeavored to make it plain and convincing to manufacturers that in the present movement there is no intention to interfere with the proper exploitation of their products, and that it does not expect them to reveal the technical secrets involved in their processes of manufacture, but that it must insist that a truthful statement concerning the actual composition, or the medicinally active components, both as regards quantity and quality, must be given, together with tests for the identification and confirmation of such medicinal constituents.

Certainly as much to be deprecated, and more harmful in their effects than secrecy in composition, are the false and absurdly extravagant claims made by some of the otherwise reputable vendors of proprietary medicines. These claims equal and occasionally surpass the claims made by "patent-medicine" vendors in their advertisements in the newspapers. During the last few years this method of advertising has grown steadily worse, each advertiser apparently wishing to outdo every other in eulogizing his particular preparation. It has finally come to pass that a plain, truthful statement regarding the therapeutic value of an article is generally considered valueless, and even reputable firms have not hesitated to make statements in their advertising literature that have been far from the truth. Many manufacturers acknowledge this and excuse themselves by saying that others have done it and they had to. They acknowledge that loose methods regarding this feature of their business have been in vogue, largely due to unchecked competition by unscrupulous concerns. We presume there is no objection to a reasonable optimism on the part of the manufacturer; but obvious misrepresentations as to the therapeutic value are quite as dishonest as misstatements concerning the composition.

Another difficulty which the Council has experienced in its investigations of synthetics, mixtures and new remedies is found in the character of the names proposed therefor. It is a recognized principle that the name proposed for a remedy should not in any way mislead or deceive. If the name, therefore, is indicative of origin, the origin indicated

must be the real one. If, on the other hand, it is indicative of quality or property, the preparation must have that quality or property. Names which, by their ending or otherwise, are indicative of definite classes of compounds, or which in any part of the name show derivation from any particular source or the possession of any particular quality, must be true to the indication. Many preparations would be excluded from classification by reason of false or misleading names.

Investigation has shown that, as a rule, the preparations placed on the market by the regular manufacturing pharmaceutical and chemical houses are as represented; at the same time we regret to state that in some instances otherwise reputable firms have been offering to the profession articles that are not in accord with the claims made for them. The Council does not think it wise to be more specific at this time, believing that these preparations will be withdrawn, or that a true statement will be made regarding their character and composition.

Investigation has also shown that certain remedies are being manufactured under patents that do not conform to the specifications of the patents.

Attention is called to the fact that occasional statements respecting the nature of the substances occurring in the mixture or methods of preparation are made by manufacturers which seem to be contrary to the established principles of chemical reactions. As an illustration of this, it may be stated that the mere mixture of two substances, which may possibly react chemically, is not properly represented by supposing that complete chemical reaction has taken place unless that actually has occurred. This is especially true of certain very complex organic compounds, which, it appears, can not possibly be made by the preparation either of the pure acids or of the pure bases, but in which attempts are made to produce the combination by mixing the substances in the crude or unmanufactured state and assuming that the chemical reactions have taken place.

In these cases the statement of the manufacturer should convey the facts of the case and not the assumed reactions.

As was mentioned in the former report, an investigation of some of the so-called cod-liver oil preparations has led the Council to believe that some of these articles are fraudulent, since they contain no cod-liver oil, and that both the public and the medical profession are being greatly deceived in many articles that are placed on the market as tasteless or fat-free cod-liver oil.

These are the features of existing conditions that are retarding the work and delaying the approval for admission of some articles which otherwise might be accepted.

The Council recognizes that sufficient time should be allowed manufacturers to make the necessary changes in their labels, circulars and printed matter to conform to the rules. July 1, 1906, has been tentatively fixed as the date when compliance with the rules be required of all preparations. It is hoped that soon after that date it will be possible to issue the first edition of the proposed book, "New and Non-Official Remedies." Although the first number will not be complete, the annual revision will afford opportunity for the admission of such articles as may not at that time have been acted on.

It is hardly necessary to remind you that there is much detail work of a chemical nature connected with this work, and while some of the members of the Council have been devoting much time and labor in this direction it is believed that some of this detail work could be done much more satisfactorily if facilities for it were provided by you at the Association building. Therefore, the Council begs to suggest that, if it is possible to do so, a chemical laboratory be established by the Association with a competent chemist in charge. There is a great amount of work to be done, and it is work that must be continued if the medical profession in the future desires to protect itself from unscrupulous promoters.

The Council reiterates its former plea to those connected with hospitals for their co-operation in making clinical tests. There has been some co-operation of this nature, but not so much as the Council wishes it could have.

The prospects for a satisfactory solution of the various questions which confronted the Council at the beginning are

more favorable as time goes on; it wishes to state, however, that the ultimate success of the work must necessarily depend largely on its endorsement by the members of the American Medical Association and by the physicians in general limiting their support to those manufacturers who are supplying them with honest preparations in a legitimate manner.

The evident appreciation of the efforts of the Council by the medical profession of the country is highly gratifying and encouraging.

Respectfully submitted,

Members of the Council on Pharmacy and Chemistry, American Medical Association.

Amenoretts.

DODGE CITY, KAN., March 9, 1906.

To the Editor:—As a slight contribution to the fight against nostrums, permit me to relate a recent experience with a detail man for a proprietary preparation made at Topeka, Kan. This man entered my office and introduced himself as the representative of "The Amenoretts Company," and laid on my desk a small box containing a number of vaginal suppositories.

He informed me, with zealous kindness, that the suppositories would cure all "female complaints" and save many a woman from the butcher's knife. He helped himself to a chair and sat down to tell me of the wonderful results achieved by his remedy.

I always listen to these men whenever I have the time, and in this case I heard the familiar tale of restored health after all other means had failed.

He had given me a circular, and this is what I read:

"Amenoretts, The Great Cure for All Female Trouble." "Amenorrhoea, leucorrhoea, displacements, ulcerations of the womb, pelvic cellulitis, peritonitis, abscess, tumors, sterility, ovarian dropsy, menopause and piles."

"For amenorrhoea, leucorrhoea, irregular or suppressed menstruation and neuralgia of the womb, use every other night."

"For enlargement and falling of the womb, use every night for three nights, thereafter every other night until cured."

"Ulceration and catarrh of the womb, use every other night."

"Pregnancy period, use once or twice a week after second month."

"Change of life period, twice a week."

"To correct non-development of young women, use three times a week."

"Conorrhoea, use every night for ten nights, or until there is a feeling of lassitude, indicating overuse of the remedy."

"Piles, insert one in the rectum every other night, pushing it well up," and so on.

I asked him what the Amenoretts were made of, and he referred me to the circular. And here is what I read:

"FORMULA OF THE SUPPOSITORY."

"The active principles of Pyroligneous Acid, Iodine, Pieric Acid, Boracic Acid, Quinine, Tetraborate of Soda, Glycerine and Oil of Theobroma."

"TABLETS."

"Pyroligneous Acid, Iodine, Boracic Acid, and Tetraborate of Soda."

I said: "There is no active principle of pyroligneous acid [wood vinegar], iodine, pieric acid or boracic acid. Quinine is itself an active principle of cinchona, while the active principles of sodium tetraborate [borax], and glycerin must have their abiding place in the vivid imagination of the writer of this very remarkable formula. But laying aside these non-essentials, I don't see any quantities specified."

"No," said my visitor, "we don't print quantities."

"Why not?"

He smiled at my evident innocence. "Because," he replied, "you'd take the formula across the street to your

local druggist and we wouldn't get to sell you any of our suppositories. Understand," he continued, "we don't sell these to the laity. We're strictly ethical."

I ignored his last remark; it contained food for reflection, and said: "I certainly shall not buy of you unless I know not only what substances are incorporated in the suppository, but how much of each substance. And I think too much of my patients to experiment on them with such a product. Are you a physician?"

He said that he was not.

"Well, if you were a physician, how do you suppose that you would feel if a man, not a doctor, should come into your office and volunteer advice with regard to the treatment of your patients with something he had to sell, the composition of which he refused to disclose?"

Not being a physician, he didn't know how he would feel under such circumstances. I asked him if he had any difficulty in getting rid of his samples. He said that there was not much, that occasionally a doctor declined them, but that did not often occur. He had recently sampled Kansas City, spending two weeks there, and during the following month he received orders for \$200 worth of the goods. And I am afraid that he told the truth.

What right has medicine to be called a learned profession when its votaries, in the use of remedies of unknown composition, exhibit a credulity that puts them on a level with the aboriginal medicine man, and far below that of the Christian scientist?

W. H. GRAVES, M.D.

Petition in Germany for Central Government Office to Examine New Remedies.

A petition has been presented to the secretary of state for the German empire asking the establishment of a central bureau whose office shall be to examine the new "patent" and proprietary medicines and apparatus put on the market for the cure of disease. The petition was signed by a large number of German physicians, manufacturing chemists, and others. The aim of the central bureau would be something like that of the Council on Pharmacy and Chemistry of the American Medical Association, except that it would be an official institution of the government. The petition cites the present abuses and the scandal of having nostrums and fake apparatus protected by government patents. It also describes with approval the work done by the mayor of Carlsruhe, who, on his own initiative, has had all the remedies which are advertised in the local papers, bill boards, or elsewhere, analyzed, and the reports published to warn the public of the danger of being swindled. The petition also refers to the way in which manufacturers continue a preparation under another name when it has been exposed. The petition owes its inception to the German Antiquackery Society.

"Patent Medicine" and the Lumberjack.

A writer in the *State Review*, published in Grand Rapids, Mich., in the issue of March 3, 1906, comments on the government's action in forcing those who retail certain alcoholic nostrums largely used for liquor to take out a liquor dealer's license, and says that this new policy on the part of the internal revenue service will affect the Michigan lumberjack in particular.

The writer says:

"In nearly all the small lumbering towns in the upper peninsula, and in the cordwood camps conducted in connection with the woods operations of the furnace companies, patent medicines of every kind are sold in immense quantities. The 'medicines' are not purchased by the thirsty individual for the purpose of alleviating physical disorder, but rather with the idea of satiating an unquenchable thirst for 'something strong.' In the cordwood camps of Alger County, where Finns and Scandinavians are employed, the most favored patent medicine is known as Hoffman's Drops, a mixture in which ether and other chemicals predominate, and produce the desired result of a stimulant much more quickly than Peruna or the average brand of stomach bitters. The 'Drops' are used almost to the exclusion of all other patent medicines, and are purchased by dealers in case lots, being as staple a commodity as flour and sugar, with the additional feature of yielding a larger profit to the dealer.

"It is not an uncommon sight in stores located near lumber or woodchoppers' camps to find from ten to fifty cases of Peruna or other patent-medicine bitters piled up in the store room. In some localities Hostetter's Stomach Bitters, Rock-candy Cough Cure or other brands are preferred, but in most instances Peruna is the general favorite with the lumberjack, and is bought more eagerly than any other. In a single carload of 'local' freight taken out of Marquette recently on a certain railroad were 150 cases of Peruna consigned to general stores at stations east of here. This single shipment was unusual, of course, coming as it did in one day, but it is given as an illustration of the amount of this 'medicine' consumed in the lumber camps for other than medicinal purposes in the immediate vicinity of Marquette. In the absence of liquor the men are willing to accept any kind of medicine that will 'have the desired stimulative effect.' Not all the men in lumber camps, however, are addicted to the habit of bitters tipping, but the majority of them will take almost any kind of nostrum when liquor is not obtainable."

Working the Doctor.

LA JUNTA, COLO., March 7, 1906.

To the Editor:—Some time ago I received from the Resinol Company, of Baltimore, a sample of their soap. Accompanying the sample was a postal addressed to their home office, soliciting the names of a few of my patients who were likely to be interested in resinol soap. Suspecting that this meant open advertising of the resinol ointment to the public, using our profession for the purpose, I sent the firm the addresses of four of my patients, telling my patients what I had done and asking them to let me see what was sent to them. In a few days all received samples of resinol soap, which, of course, it was perfectly proper for the firm to send, but mark the sly way of advertising resinol ointment direct to the public, using me as their unpaid agent for the purpose. I enclose two circulars. One refers to the soap and, while extravagant claims are made for the soap, there is nothing otherwise objectionable in the circular. The second circular, however, is a different proposition. This circular calls special attention to resinol ointment and contains testimonials from thirteen physicians and one dentist. How a layman can read this circular and these testimonials without being convinced that resinol ointment is the greatest thing on earth for about everything that could happen I do not know. Judging by the circular it certainly has the indorsement of the medical profession, and the layman is told by physicians that it is good for erysipelas, all kinds of local inflammation, such as burns, boils, mammary abscesses, eczema of all kinds, herpes zoster, pruritus ani, pruritus vulvæ, hemorrhoids, scald head, cold sores, red and inflamed nose (although we are told in parentheses that it will not apply in this regard to the red nose caused by alcoholism), fetor of feet or offensive perspiration, or any morbid exudation.

I realize that this particular instance is only one of thousands that are going on all the time. Physicians are "worked" for a testimonial, and after they have given the testimonial they are then "worked" to distribute them to the public so that the public can buy the stuff direct; for why should they go to a doctor when all doctors apparently say that resinol ointment will cure all skin diseases, besides several other things.

Is it not about time that we physicians realized how we are being humbugged and utilized by these proprietary men?

E. GARD EDWARDS.

Some More Endorsements.

Dr. Oscar F. Mayer, City of Mexico, writes:

"My congratulations to the good work of the Council on Pharmacy and Chemistry, which is appreciated by an old Ph.G."

Dr. B. E. Miller, Albion, Ind., writes:

"I like that reform movement dealing with drugs, and feel deeply interested in the reports."

Dr. S. H. Landrum, Whitewright, Texas, writes:

"I am enthusiastic for clean pages and scientific text. . . . THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION gets better every year. Its absolute independence is its great advantage."

Dr. C. L. Upton, Shelburne Falls, Mass., writes:

"I commend most heartily the good work THE JOURNAL is doing in the exposure of the 'patent medicine' fraud and the equally bad or even worse proprietaries. I have stopped my subscription for several journals because of the advertising they carry. If all the members of our profession would make their protests in this way we would soon correct the evil so far as the medical journals are concerned.

"I wish to add a few words about Chamberlain's Colic, Cholera and Diarrhea Remedy. Two weeks ago I was consulted by a railroad telegrapher who had been taking his medicine for the past two years. He began it for a diarrhea and has become addicted to it. He now takes from two to four ounces nightly (he is a night man), and has become a complete nervous wreck. This case needs no comment of mine; it speaks for itself. Let the good work go on."

Dr. T. E. Keeler, Lebanon, Ohio, writes:

"Your crusade against 'patent' and proprietary medicines is doing great good. Publicity is what is needed."

ACTION BY MEDICAL SOCIETIES.

At a meeting of the Kaufman County (Texas) Medical Society, held February 6, resolutions were adopted indorsing the action of the American Medical Association in establishing the Council on Pharmacy and Chemistry, and commending the educational campaign being carried on by the *Ladies' Home Journal* and *Collier's Weekly* in exposing the subserviency of the press to the Proprietary Association of America and the methods of this organization in exploiting remedies. The resolutions also condemned the prescribing of preparations of unknown composition.

At a meeting of the Bucks County (Pa.) Medical Society, held February 14, resolutions were adopted indorsing the stand that has been taken against nostrums and "patent medicines" by THE JOURNAL of the American Medical Association, *Collier's Weekly*, the *Ladies' Home Journal*, the *Druggist's Circular*, the *Farm Journal*, and other publications, and approving the work of the Council on Pharmacy and Chemistry in exposing the nature of many much lauded preparations, and recommending physicians to refrain from prescribing these remedies and from subscribing for or contributing to any medical publication under the control of nostrum manufacturers and vendors. The society also approved the bill to regulate the manufacture and sale of proprietary remedies drafted by the *Ladies' Home Journal*, and suggested that a national commission be created to investigate remedies and to pass judgment on their therapeutic value.

Similar resolutions were passed by the Rhode Island Medical Society, and the Lenawee County (Mich.) Medical Society.

At a meeting held February 21 the New Haven Medical Association decided to appoint a chemist to analyze secret and "patent medicines," provided it can be done without expense to the association.

At a meeting of the Madison County (Texas) Medical Society, held March 13, the following resolutions were adopted:

WHEREAS, The American Medical Association, through its Committee on Pharmacy and Chemistry, is making a heroic and much-needed war in defense of the decency and dignity of American medicine for the benefit of the people of the United States against the corrupt, unscrupulous, avaricious and shameless system of nostrum prescribing, advertising and selling; Therefore be it

Resolved, That the Madison County Medical Society heartily approves the work already accomplished by said Committee on Pharmacy and Chemistry and hopes for a continuance of same.

Resolved, That it condemns the slovenly, ignominious, unscientific and fraudulent practice of prescribing and advertising secret remedies of any kind, whether designed for the use of physicians or the public.

Resolved, That the bill, republished in the March (1906) number of the *Texas State Journal of Medicine*, under the caption "Mr. Bok's Patent Medicine Bill," meets with the approval of the society.

Resolved, That the delegates to the next meeting of the Texas State Medical Association are hereby instructed to have these resolutions read to that body and to ask for proper consideration.

At a meeting of the Evanston Branch of the Chicago Medical Society resolutions were adopted endorsing the work of the Council on Pharmacy and Chemistry of the American Medical Association, and urging that the present campaign of publicity be continued unremittently. The society also urged members to refuse to sanction in any way the use of any remedy the formula of which is not definitely known, and recommending the careful investigation of the methods of false advertising carried on by so-called medical specialists whereby the public is defrauded, and recommended that in this case also a campaign of publicity be inaugurated.

Medical Legislation

Governmental Department of Health.

Dr. M. W. Gray, Secretary of the Oakland County (Mich.) Medical Society, informs us that at a regular meeting of the society at Pontiac, March 13, 1906, the following resolution was passed:

WHEREAS, The public health problems of this country are of strictly fundamental importance and underlie success in agriculture, manufactures, commerce and every other branch of human activity as was shown in Cuba, where successful military operations depended on the work of the sanitary corps; as was shown in New Orleans, where the commerce of a city and of a great section of the country was paralyzed pending the suppression of an epidemic, and is being exemplified by the brilliant achievements of Colonel Gorgas in the Isthmus of Panama, where the gigantic operations of engineering stand at rest until successful sanitation makes their presentation possible. Therefore, be it,

Resolved, That if it is the sense of the Oakland County Medical Society that a department of health, with representation in the Cabinet of the President, ought to be established, such a department to embrace an expansion of the present Public Health and Marine-Hospital Service, with the addition of other public health agencies now existing and in operation in other departments of the government, together with such other agencies and functions as may best subserve the public welfare.

The Vermillion County (Illinois) Medical Society, at its meeting at Danville March 12, with a membership of seventy-one representative physicians, voted unanimously in favor of the creation of "A Department of Public Health with Representation in the Cabinet."

The Society also voted unanimously in favor of all the subjects recently referred to the auxiliary committee, with the exception of "The Bill to Restore the Canteen in the Army," which received a unanimous opposition vote.

Bills in New Jersey Legislature.

During the present session of the legislature of the state of New Jersey a number of bills have been introduced which are of interest to the medical profession. One provides for a laboratory for the manufacture of diphtheria antitoxin and for its free distribution through local boards of health. Provision is also made for the appointment of sanitary inspectors, health officers and statisticians for the bureau of vital statistics. An appropriation of \$20,000 annually is asked for to insure the securing of pure foods, drugs, medicines, etc.

The most important bill is one providing for the regulation of the sale of drugs and for the inspection, analysis and regulation of their manufacture. We quote section one in full: "No person shall manufacture, sell or offer or expose for sale or give away any proprietary medicine or other medicinal preparation containing alcohol, opium or any of its preparations, its alkaloids or their derivatives, nux vomica and its alkaloids and their derivatives, digitalis, chloroform, cannabis indica, chloral or any of its derivatives, bromids, cocaine or any of its salts, eucain or any of its salts, acetanilid, antipyrin, bromoform, exalgin, holocain, phenacetin, phenocoll, sulphonal, trional, veronal or any other hypnotic, anesthetic, analgesic or cordial, circulatory, respiratory or nerve depressant unless the same shall have plainly and conspicuously stamped or printed on the bottle, box or receptacle containing the same, or on the label affixed thereto, and also on the outside wrapper or package, if any, and also in the inside wrapper and on all circulars accompanying said medicine or medicinal preparation and relating to it, if any, a true statement of the percentage of alcohol and the percentage or proportion of each of the other above-mentioned or described drugs contained in each bottle, box, receptacle or package of such medicine or medicinal preparation."

ration. Such information shall be stamped or printed in antique or gothic type, easily to be read, of a size not smaller than that known as ten-point, and so displayed as to be conspicuous. Where alcohol is used as a solvent, vehicle or preservative, or for any other purpose, it is to be deemed as contained in the medicine or medicinal preparation within the meaning of this act, and the drugs above mentioned or specified shall be described by their common or English names."

The term medicinal preparation as used in the bill is intended to include every preparation or combination or mixture of drugs, or of drugs with substances which are not drugs, when such preparation is said to have medicinal properties or to be a remedy or medicine or cure or food, or is intended to be used for medicinal purposes. The act does not apply to preparations intended solely for external use.

The Patent-Medicine Bill in New York.

AN INTERESTING HEARING.

The senate and assembly committees on public health held a public hearing jointly on the Stevens-Wainwright Proprietary Medicine Bill (Senate No. 258, Assembly No. 456), in the capitol at Albany, N. Y., March 14.

This bill provides that proprietary medicines which contain alcohol, opium or any of its preparations, its alkaloids or their derivatives, strychnin, digitalis, chloroform, cannabis indica, chloral or any of its derivatives, bromids, cocain or any of its salts, eucain or any of its salts, acetanilid, antipyrin, bromoform, exalgin, holocain, phenacetin, phenocoll, sulphonal, trional, veronal or any other hypnotic anesthetic, analgesic or cardiac, circulatory, respiratory or nerve depressant, shall be so labeled as to reveal the presence and percentage of those ingredients.

Only seven persons appeared in opposition to the bill, viz., George L. Douglass, attorney for the Proprietary Association; Mr. Muir and Mr. Rogers, for the New York State Pharmaceutical Association; Mr. A. C. Searles, Mr. Peter Diamond and Mr. George Leauan, retail druggists. In behalf of the drug section of the New York City board of trade, Mr. Peters offered a substitute bill, of entirely different scope, viz., a bill to prohibit the sale of cocain, eucain, opium, morphin, heroin, chloral hydrate or any salt or compound of any of the foregoing substances, or any preparation or compound containing any of them, except on physician's prescription.

Two of the objections made to the Stevens-Wainwright bill had already been foreseen by the committee for safeguarding the sale of narcotics, under whose auspices the bill was introduced, and amendments had already been prepared to cover the objections, viz. (1) that to guard against injustice arising from the possibility of errors in analysis, the results of analyses should not be published by the State Department of Health until after thirty days' notice to the manufacturer. (2) The other objection was against the general descriptive words intended to cover new variations of coal-tar derivatives. The proposed amendment is to strike out those words and insert a provision authorizing the State Board of Health to add to the drugs enumerated in the bill, from time to time, as it may deem necessary for the protection of the public health. This is in accordance with the powers already conferred by statute on the State Department of Health with reference to additions to the poison list.

Mr. Douglas, for the Proprietary Association, argued that the bill meant "destruction, not regulation." He received his answer later, that such an assertion was tantamount to an admission that many of the preparations on the market which he was employed to defend were of such a nature that the public would refuse to buy them if it knew their contents.

He argued that the bill discriminated between proprietary preparations and medicines listed in the Pharmacopœia, that a Pharmacopœia preparation might contain 90 per cent. alcohol and be sold without labeling, while proprietary medicines which contained a small amount of alcohol, for example, 5 per cent., would come under the law. The obvious answer was made that the object of the bill was publicity. The ingredients of Pharmacopœia preparations are known and they are properly excepted from the operation of the bill, as there is no desire to interfere with legitimate drug business.

Mr. Douglas argued that the bill was intended to prejudice the public mind against proprietary medicines; that alcohol was necessary as a solvent and to prevent freezing and precipitation. That proposition was met by a statement that the bill does not prohibit the use of alcohol nor attempt to limit its use or to condemn or in any wise criticise the use of alcohol, but simply provides that its presence shall be made known.

Mr. Douglas laid great emphasis on the fact that the users of proprietary medicines were not there advocating the bill, but Mr. William A. Jenner disposed of this argument effectively by reminding the committee that the users of those remedies were ignorant of their contents, and that while they were not there asking for legislation, neither were they present to oppose it.

A. A. Seymour, secretary of the State Department of Health, said he represented the commissioner of health. He advocated the bill. Said the department desired it and would enforce it.

The importance of the subject was well attested by the presence of so many distinguished men in favor of the bill, as follows: Mr. William A. Jenner, Dr. A. Jacobi, Dr. W. Gilman Thompson, Dr. Egbert Le Fevre, Dr. Arthur T. Root (representing the New York State Medical Society); Dr. Wisner R. Townsend, Dr. Albert Weston, Dr. Arthur T. Holding (Albany County Medical Society), William Jay Schieffelin, Ph.D. (of Schieffelin & Co., manufacturing druggists), Samuel Hopkins Adams (of *Cullier's Weekly*), Rev. Hervey Wood (representing National Temperance Society and delegated to represent all the Baptist organizations in the state), Mrs. Frances W. Graham (president New York State Woman's Christian Temperance Union, representing nearly 900 unions and about 26,000 members in the state), Rev. John M. Trout (delegated to represent all the churches of the Westchester presbytery), Homer Folks (delegated to represent the State Charity Organization Society), Edward T. Devine (delegated to represent the Charity Organization Society), Seth B. Robinson, Alfred L. Manierre.

Correspondence

Poison Ivy.

BUFFALO, N. Y., March 17, 1906.

To the Editor:—Referring to the discussion in regard to *Rhus toxicodendron* and *Rhus coccinea* in your issues of January 27 and March 17, and intervening issues, I would like to make some observations and to ask some questions. I seem to be immune. When a little boy, spending the summer vacations on a farm, I repeatedly tried to poison myself by walking through patches of ivy barefoot, and even rubbing it into the skin and into abraded places, but failed in a number of trials in several summers. My object was to exchange the hygienic advantages and loneliness of the country for the more familiar disadvantages of the city. For a number of years afterward I did not hesitate to handle the plant freely, and was never poisoned. Since arriving at years of relative discretion I have avoided the plant as a matter of ordinary caution, but have not hesitated to walk through it, and have often touched it accidentally without harm.

In several summers' experience as physician at a boys' camp I never encountered a marked case of poisoning, although I have seen it produce urticaria-like wheals that promptly disappeared after washing with plain water. As a matter of precaution the boys were assembled at the beginning of each encampment and warned against the two poisonous rhoses, *Solanum dulcamara*, etc. Many cases of poisoning are due to confusion with Virginia creeper, *Ampelopsis quinquefolia*. A good way to impress the difference on children is to tell them that they can safely shake hands with the plant that has five leaflets, corresponding to their five fingers, but not with the three-leaved plant.

I have known of bad cases of poisoning due to the use of *Rhus toxicodendron* in place of toilet paper, and one of my friends was terribly poisoned in winter by a homeopathic physician who ordered the tincture in a liniment for some form of rheumatism.

Can anyone state from actual experience whether poisoning occurs from conveyance by wind, and whether dermatitis tends to occur a year later without fresh exposure? Both of these claims seem absurd, and yet I am credulous enough to accept any statement, however absurd, if it can actually be proved—and some things that have seemed absolutely absurd have been proved.

A. L. BENEDICT, M.D.

CINCINNATI, OHIO, March 16, 1906.

To the Editor:—In the current issue of THE JOURNAL A. W. Balch, Washington, passed assistant surgeon, United States Navy, takes exception to my article on "Dermatitis Venenata," abstracted in THE JOURNAL. He says that while I have had *Rhus toxicodendron* poisoning twice he has had it eighty times. He queries: "Is it possible that the work of Pfaff is not yet known to the profession?" Had he read the original of my article, not the abstract, he would have seen full reference to Pfaff and his work. I should be pleased to read Dr. Balch's experiences with his eighty cases of poisoning from *Rhus toxicodendron* more fully written up.

E. S. MCKEE, M.D.

Quinin in Pneumonia.

NEW RICHMOND, OHIO, March 16, 1906.

To the Editor:—In 1874 I read, at a meeting of the American Medical Society in Cincinnati, my translation of an article from "Volkmann's klinische Vorträge," written by Jurgenson in 1872, in which he advocates the use of large doses of quinin in the treatment of pneumonia in conjunction with cold water baths. He gave from 25 to 40 grains at one dose, or if this was not advisable owing to an idiosyncrasy of the patient, he divided the dose in three or four equal portions, giving each at intervals of fifteen or twenty minutes, but so that the entire quantity was taken within an hour, or the reduction of temperature would not take place. I followed out this quinin treatment for two years, but found that it did not influence the course of pneumonia either favorably or otherwise, and it was often followed by such unpleasant symptoms of cinchonism that I desisted, and have not used the method since.

R. F. ERDMAN, M.D.

Staining of Conjunctiva by Argyrol.

DOYER, N. H., Feb. 28, 1906.

To the Editor:—In a pamphlet sent out by the manufacturers of Argyrol I find the following statement: "Argyrol is the only silver salt that does not permanently stain the conjunctiva. It may be used with safety by patients themselves, as often as required."

Last week a patient appeared in my office who had been using a 10 per cent. solution of Argyrol in the left eye for nearly a year. It was originally prescribed by a competent oculist, but, of course, with the intention that it should only be used for a short time. I took pains to hunt up the original prescription to be sure that it was Argyrol.

In this case the bulbar conjunctiva, the caruncle, and the lining of the lid were as badly stained as from the prolonged use of a solution of nitrate of silver.

LOUIS W. FLANDERS.

The Pure-Food Bill Board of Experts.

ANN ARBOR, MICH., March 18, 1906.

To the Editor:—Your editorial stricture on the provision in the amendment to Section 9 of the Hepburn bill providing for the appointment of a board of experts to pass on the wholesomeness or unwholesomeness of preservatives would be just if it were true, but you were laboring under a misapprehension when you made your editorial statement. You say that the decision of the board is final and that there is no appeal to the courts or to the Secretary of Agriculture. This is all wrong. The board of experts is selected by the Secretary of Agriculture, and he is instructed by the law to appoint disinterested men; the Secretary fixes the compensation allowed members of the board and he may accept or reject their findings. The Secretary of Agriculture, and he alone, is given the authority to render decisions, and even his decisions are of no further value than for "the guidance of officials charged

with the administration of food laws and for the information of courts." The statement that no appeal from the findings of the board can be made in the courts is too puerile to deceive anybody. In this country, no one, not even a food manufacturer, can be convicted without a trial, and Section 6 of the Hepburn bill makes it plain that before any preservative can be condemned it must be shown by the prosecutor that it is poisonous or deleterious to health, and in such a trial the prosecutor and the defendant both have the right to bring forth whatever evidence each is able to produce. The findings of the board of experts as provided for in the amendment to Section 9 in such a trial may benefit either the prosecutor or the defendant, and either certainly would have the right to support or to combat the findings of such a board. The sole object in the amendment is to provide the Secretary of Agriculture with the best advice possible. A committee of agricultural chemists constitutes a suitable body for determining methods and standards for chemical analyses, but agricultural chemists are not fitted by their specialty to determine the effects of preservatives on the human body. It seems unnecessary to argue this point farther.

V. C. VAUGHAN.

[With all due respect to Professor Vaughan, and recognizing the fact that he is thoroughly conversant with the subject, we are still of the opinion that the clause to which we objected last week is vicious. Our readers, however, may judge for themselves. The clause will be found in section 9 of the bill, which was published last week.—Ed.]

Miscellany

The Record of the House.—Each house in Paris now has to have its sanitary record. It is something like a bank book or portfolio for each individual house. The cover bears the subdivision, ward, street and number, and inside is a small plan of the house, with designation of all drain pipes, cess pools, etc. A loose sheet contains a description of the house, another contains a record of all the cases of communicable diseases that have occurred in the building, and the deaths from them, recorded as they occur. Another sheet records the disinfections done on the premises, with dates and causes. One or more sheets contain the record of the changes ordered by the bureau of hygiene, and the record of the compliance with these orders. One or more sheets further contain the results of sanitary inspection of the house. All these house books for one street are kept in an envelope or box, which has a record on the outside of the length and width of the street, number of houses, number of inhabitants, system of sewerage, water pipes, etc. P. Juillat is chief of the bureau d'assainissement de l'habitation et du Casier sanitaire des maisons de Paris, and thus has charge of all this work. It is part of the police department. He describes its workings in the first number of *Hygiène Générale et Appliquée*, Jan., 1906, and discusses the expense of introducing a system of "house books" (casier sanitaire). A French law of 1902 ordered the formation of a bureau of hygiene in every town of 20,000 inhabitants or over, and he assumes that the officials of this bureau will do the work necessary for the compiling of the records of each house. The first expense will not be much more than twenty cents a house, and, once installed, the expense of maintenance will be trifling. The Paris authorities are much gratified at the way in which the system is working, although scarcely more than commenced there.

Fallacies in the Clinical Diagnosis of Gonorrhea.—Dr. G. Frank Lydston, Chicago, in a paper read before the Mississippi Valley Medical Association, said that the most dangerous type of infection of the female is that in which the external manifestations of the disease are absent or wanting. Gonorrheal urethritis in the female in the chronic form may present no secretion whatever on external examination. There may be little or no vaginal, cervical, or uterine discharge, and even such as there is may, on examination, fail to disclose the micro-organisms of gonorrhea. Notwithstanding this, the mucous glands may be involved, and under the influence of sexual excitement and the mechanical effect of coitus the

physiologic hypersecretion might convey to the meatus gonocoei in abundance. The result is obvious. It seems to Dr. Lydston that it is impossible for a physician to state in any given case that a woman is free from infection. This is one of the strongest arguments against regulation and medical inspection of prostitutes. He entertained serious objections to the medical profession constituting itself an assurance society for the protection and promulgation of the social evil, but aside from this scruple there remains the fact that no reliable system of inspection or examination can be devised. In many cases of infection of healthy women by a latent gonorrhea of the husband, mixed infection is responsible, and the resulting pathologic condition in the female is non-specific. Its being non-specific, however, does not preclude the possibility of its becoming very serious. Dr. Lydston thinks that there are no tests which will enable the physician to give a positive opinion of the infectiousness of a given case of suspected latent gonorrhea. The clinical history in many cases is more important than the laboratory study of the case, and a careful combination of both methods of study is always essential. The physician should be as chary of assuming responsibility in advising a gonorrhea in the matter of matrimony as he should be in advising syphilites under similar circumstances.

Injuries from Quack Practices.—The German Antiquackery Society has been diligently collecting instances of injury from quack practices that have come under the personal observation of its members. A list has just been published in the organ of the society, *Hygienische Blätter*, for February. It includes 91 cases of severe injuries, terminating fatally in 37. All the particulars are on file at the society's office. (See page 453.) In one case inflammation of the pelvic connective tissue was treated by a quack with daily energetic massage, resulting in fatal septicaemia. In another an ovarian cancer was said to be the pregnant uterus and was massaged until too late for its removal. In another case a tubal pregnancy was treated as "colic." An incipient cancer of the cervix, diagnosed by a physician with the microscope, was treated by a quack with hydrotherapy, massage and electricity until it became inoperable. In 27 cases of serious injury resulting from quack treatment of surgical lesions 9 resulted in death from septicaemia, including 1 death from general sepsis after a small wound on the finger had been treated with bone sawdust compresses for a long time. Two cases of incarcerated hernia resulted in fatal gangrene after being treated with sandbags in one case and with tea and water in the other. One individual succumbed to the effects of necrosis of the bone after a knee lesion had been long treated with a plaster spread on pieces of newspaper. Another with hip-joint affection, treated with vigorous massage, succumbed to a resulting meningitis. One child died in consequence of a salve having been rubbed into its eye by a quack, and another was rendered blind. The cases are numerous in which cancers were allowed to become inoperable by wasting time with irregulars. The editorial concludes with the remark that many persons who have come to grief in the hands of irregulars are ashamed to confess it to the physician to whom they apply afterward. Others exonerate the quack for the evil results of his practices. One case is known in which a woman had been treated for cancer and her testimonial to her cure was repeatedly published in the papers. Investigation showed that she had died long since of her cancer. The quacks included magnetopaths, nature healers, untrained midwives, bone-setters, barbers, herb doctors, etc. Four were druggists, some of whom diagnosed and treated by letter.

Analyses of Food Products in Kansas.—In the January *Bulletin* of the Kansas State Board of Health Prof. E. H. S. Bailey, state chemist, reports on adulterations. Having stated that many adulterants are harmless and are intended to increase the bulk or weight, at the customer's expense, while others are positively injurious, even poisonous, Prof. Bailey gives the results of his analysis of a number of samples of food, including flavoring extracts, preserved fruits, syrups, vinegar, nitrogenous foods, and baking powders. Of twenty-five articles tested he found twenty-one adulterated. He found a sample of "Puritan" brand extract of lemon to be destitute of oil of lemon and colored with a coal-tar dye.

Extract of vanilla, "Puritan" brand, "strictly pure," he reports contained none of the natural resins of the vanilla bean. "Silver Leaf" tomato catsup he found to be artificially colored and preserved with salicylic acid. He reports that a pint glass can of strawberry, "Orchard" brand preserve, was dyed red with a coal-tar dye and sweetened with glucose. A few small strawberries were scattered through it. "Absolutely Pure Canada Sap Maple Syrup" he discovered was cane sugar, a much cheaper article, and therefore a fraud on the customer. On analysis, two bottles of vinegar, one called "White Vinegar" and the other "Wine Vinegar," were found to be artificially colored distilled spirit vinegars. He reports that "The Kansas City Baking Powder, Absolutely Pure," and Shepard's "Economical Absolutely Pure Baking Powder," among others, were alum phosphate mixtures—perhaps pure in the technical sense, but not in the pure food sense.

Sanitary and Moral Prophylaxis.—In the *Boston Medical and Surgical Journal*, Feb. 8, 1906, Dr. William L. Holt urges the organization of a state society on venereal prophylaxis. A year ago in New York the American Society of Sanitary and Moral Prophylaxis was founded. Similar societies already existed in Germany, Holland, and other European countries. The object of these societies is to limit the spread of diseases which have their origin in the social evil, and to study the best means of every order, moral, legislative, social and medical to be employed in the prevention of these diseases. Dr. Holt suggests a campaign of popular education similar to the anti-tuberculosis campaign. The ignorance of the masses, especially young people, concerning sexual hygiene, is deplorable. A system of education, whether at home or at school, is incredibly stupid if it leaves our children in darkness concerning the laws governing sexual function and the ravages and terrible consequences of venereal disease. Tainted and degenerate offspring, sterility, and abortion are among the strongest agents for race suicide. There should be a state branch of the national organization in every state in the union. It is a service which the medical profession owes to society to spread all the scientific information possible concerning this delicate and important matter.

Treatment of Chancroid by Heat.—E. Welanders of Stockholm, describes in *Wiener klin. therap. Wochenschr.* the method which he has employed for many years in the treatment of soft chancre by the prolonged application of warmth. He uses in the hospital an apparatus by which continuous circulation of water of regulated temperature is carried over the surface of the ulcer, which has been prepared by curetting away the sloughing material and thoroughly cleansed. A layer of moist cotton wool is first applied, then the lead tubes, which can be bent to suit the surface, then another layer of moist cotton, the whole is then warmly packed and secured with a bandage, which can be removed and renewed three or four times daily for the needs of urination and defecation. Two days' application may suffice, but it is better to keep it up a little longer, or if it is discontinued, to use warm boracic acid lotions until healing is complete. In private practice he allows the patient to make his own moist warm applications, either immersing the part in water at 50 C., or using frequently renewed applications of cotton soaked in water at 50 to 55 C. In either case the applications should be made at least four times a day and kept up for 15 to 20 minutes each time. After each one the ulcer should be dried and iodoform applied. The heat treatment has also been employed with good results for other foul sores (non-syphilitic) of the anogenital region. He has also used it in herpes tonsurans, but here a somewhat higher temperature is required on account of the somewhat greater resistance of the germs and spores.

Treatment of Typhoid.—As to medicines, the passing years have lightened my armamentarium greatly. The coal-tar antipyretics ought rarely to be used, for while their immediate effect may be good, their ultimate influence on the heart is bad. As Dr. Baruch of New York, the great hydrotherapist, has so facetiously put it, "their chief virtue is that they enable the patient to die with a normal temperature." On this account I prefer to reduce the temperature, when excessive, by hydrotherapy, using tepid or cool sponging if the temperature be between 101.5 and 102; the cold pack, cool affusions, or the

cool or graduated bath, if it be above 103. If the temperature is below 101.5 degrees, I believe the patient is better left undisturbed. Cold to the head, by ice-bags, Leiter's coils, or water compresses, is a valuable adjunct. The value of these measures lies in four directions: First, lowering of temperature; secondly, as a nervous sedative; thirdly, general tonic effect on the heart; lastly, a lowered death rate.—Van Zant, in *Denver Medical Times*.

Tuberculosis Dispensary at Madrid.—V. Montenegro publishes an interesting series of notes in the *Siglo Medico*, Nos. 2626-8, taken during two years' workings of the Antituberculosis Dispensary at Madrid, with 1,000 tuberculosis patients. The majority were between 20 and 30 years old, or from 30 to 40, with over 2 per cent. under 10, and over 14 per cent. between 10 and 20 and between 40 and 50. About 66 per cent. of the patients had no tuberculous family antecedents. In 50 per cent. of all the patients the chest measure was equal to or more than half the height. In a number of cases of hemoptysis it proved to be the result of mitral stenosis. The lungs presented physical signs suggesting a tuberculous lesion, probably from compression of the lung by the dilated auricle, but repeated examination and radioscapy failed to reveal any tuberculous process. Such patients were generally women.

Double Nephrotomy for Kidney Stones.—M. Dezarlo describes some unusual circumstances attending the removal of four kidney stones weighing 45 gm., nearly 625 grains, from a woman of 28. The pains and discomfort were always in the left kidney, and a radiogram showed the four stones plainly. The operator did not see the radiogram and consequently he opened up the left kidney, finding it sound and free from stones. Examination of the radiogram then revealed that the stones were in the "silent" right kidney. All disturbances ceased after the nephrotomy, and nothing further was attempted for seven months, when recurrence of pain compelled intervention on the other kidney. The stones were found as shown in the radiogram and easily removed, with the rapid recovery of the patient. They consisted principally of calcium phosphate.—*Siglo Medico*.

Bars to Therapeutic Progress.—"In the domain of science every fact is a legal tender." Publicity is essential to progress. In medicine secrecy stultifies the calling and its followers, making it the only learned profession of the age which in so far, yet lingers in the embrace of the middle ages. Obviously no real therapeutic progress is possible where the prescriber and the world is informed only that the triumphant conduct of a certain case from death's door to convalescence has been wrought through the mediumship of "Puffer's Preposterous Painfugine," with the composition of which the enterprising manufacturer has not seen fit to entrust the complacent prescriber.—Jackman, in *Jour. of Medicine and Surgery*.

Sectarianism Harmful.—The realization that sectarianism is restrictive rather than helpful, that it divides and weakens, where union and strength are needed, has made the great majority of physicians in all ages desire a united profession. They have sought to avoid the use of any term that would imply a school or sect.—*Columbus Medical Journal*.

Association News

Member or Subscriber.

In the American Medical Directory, now being prepared for the press, members of the American Medical Association will be designated by the symbol *. There are a number of physicians taking THE JOURNAL as subscribers who are eligible to membership. Any one in doubt as to whether he is receiving THE JOURNAL as a member or as a subscriber can refer to the address label on the wrapper of his JOURNAL; if the month and year appear, such as "7-1-06," it means that the name is on the list of subscribers; if only the year "06," or no date at all appears, the name is on the membership roster. On advertising page 40 in this issue is an application blank, and any subscriber who is eligible, desiring to become a member, can be transferred to the membership roll by signing the

application, having it certified by the secretary of his state society and forwarding it, together with receipt for current year's subscription, or a remittance covering the same, to the American Medical Association, 103 Dearborn Avenue, Chicago.

Marriages

LAWRENCE H. BRUNDAGE, M.D., to Miss Martha Glatfelter, both of Xenia, Ohio, March 1.

OSWALD O. KAUFER, M.D., Newbern, N. C., to Miss Lilian May Taggart, at Baltimore, March 7.

JOHN U. CALHOON, M.D., Follansbee, W. Va., to Mrs. Elizabeth Witmer, at Darlington, Pa., March 5.

HENRY KREIDER, M.D., New York City, to Miss Charlotte Louise Mascare of Monroe, Mich., March 6.

EDWARD W. HANLON, M.D., Marysville, Cal., to Miss Mamie Kelly of Napa, Cal., in New York City, last week.

JAMES E. MADRUX, M.D., Sebastopol, Cal., to Mrs. Eugenia Cantel Towne of Petaluma, at San Francisco, March 12.

Deaths

Peter Van Pelt Hewlett, M.D., New York University, New York City, 1868; a member of the Essex District (N. J.) Medical Society; president of the Newark Medical Association in 1871 and 1872, and its secretary in 1869 and 1870; for several years a member of the Newark Pathological Society, and for a long time secretary and curator of the New Jersey Academy of Medicine; from 1868 to 1874 attending physician at the city dispensary; in 1873 attending physician and curator of St. Michael's Hospital; from 1879 to 1891 county physician; for many years visiting physician at the Newark City Hospital, and a member of the board of education from 1876 to 1883, died at his home in Newark, March 13, after an illness of nearly a year, believed to be malignant, aged 59.

Leonard Lawsbe Skelton, M.D., Northwestern University Medical School, Chicago, 1889; professor of nervous and mental diseases at the Illinois Medical College; professor of internal medicine and physical diagnosis, Chicago Clinical School; professor of physiology, Chicago College of Dental Surgery; for several years a member of the staff of the Illinois Eastern Hospital for the Insane, Kankakee, died at his home in Chicago, March 14, from uremia, after an illness of three days, aged 42.

Alvin Thayer, M.D., Medical College of Louisiana, New Orleans, 1845; a member of the American Medical Association and of the Medical Society of the State of Pennsylvania; one of the best known physicians of Erie, and a member of a distinguished family of physicians extending back several generations; surgeon of the One Hundred and Forty-fifth Pennsylvania Volunteer Infantry during the Civil War, died at his home in Erie, March 11, after an illness of more than a year, aged 81.

Joseph Vincent Ricketts, M.D., Miami Medical College, Cincinnati, 1891; son of Dr. Girard Robinson Ricketts, and brother of Drs. Edwin S. and B. Merrill Ricketts of Cincinnati; a graduate of the United States Naval Academy, Annapolis; for several years a practitioner of Cincinnati, died at his home in Gas City, Ind., March 12, from pulmonary edema, after a brief illness, aged 39.

Elizabeth N. Bradley-Bystrom, M.D., University of Paris, France, 1887; formerly a practitioner of New York City, and a member of the New York Academy of Medicine, New York County Medical Association, New York Pathological Society and New York Neurological Society, died at her home in Dobbs Ferry, N. Y., March 9, from paralysis, after a long illness, aged 53.

Fordyce H. Benedict, M.D., Albany (N. Y.) Medical College, 1868; the dean of the medical fraternity of Weedsport, N. Y.; a veteran of the Civil War, and a member of the Cayuga County Medical Society, died at his home, March 8, from pneumonia, after an illness of three weeks, aged 61.

John B. Brown, M.D., Medical College of the State of South Carolina, Charleston, 1858; a member of the Medical Society of the State of North Carolina and of the Robeson County Medical Society, died at his home in Ashpole, N. C., December 31, after an illness of a month.

Grove Spooner Beardsley, M.D., medical director United States Navy, retired Jan. 2, 1900, with the rank of rear admiral; a member of the American Medical Association; a veteran of the Civil War and of the Spanish-American War, of Syracuse, N. Y., died in Atlantic City, N. J., March 8, aged 68.

Earl V. Rowe, M.D., St. Louis College of Physicians and Surgeons, 1893, of Gila Bend, Ariz., physician to the Southern Pacific Railway at that point, died in St. Mary's Hospital, Tucson, March 8, from tuberculosis, after an illness of four years, aged 32.

Shelby M. Dodson, M.D., St. Louis Medical College, 1864, postmaster of Santa Clara, Cal., for four years, and for many years a practitioner of Santa Clara and San Jose, died at his home in the latter city, March 4, after a long illness, aged 67.

Lauren T. Holland, M.D., College of Physicians and Surgeons, St. Joseph, Mo., 1882; coroner of Los Angeles County from 1889 to 1903; a veteran of the Civil War, died suddenly at his home in Los Angeles, March 6, from heart disease, aged 62.

Garrett D. Buckner, M.D., Jefferson Medical College, Philadelphia, 1864; for many years a practitioner of Petersburg and Tallahoma, Tenn., died at the home of his son-in-law in Nashville, January 21, after an illness of five months, aged 65.

William Harper Sherwood, M.D., Cleveland Medical College, 1855, one of the most prominent practitioners of Painesville, Ohio, died at his home in that city March 10, from pneumonia, after an illness of less than a week, aged 73.

Charles Edward Estes, M.D., Bellevue Hospital Medical College, New York City, 1868, a veteran of the Civil War, died at his home in Columbus, Ga., March 6, from ptomaine poisoning, after an illness of two days, aged 63.

Ellijah L. Irvine, M.D., Willamette University, Medical Department, Salem, Ore., 1883, formerly a practitioner of Portland, Ore., was found dead, March 12, at his room in the Lick House, San Francisco, aged about 45.

James Hyser Hill, M.D., University of Louisville, Medical Department, 1850, assistant surgeon of the Thirtieth Missouri Volunteer Infantry during the Civil War, died at his home in Springfield, Ill., March 6, aged 81.

Benjamin R. Pearson, M.D., Medical College of Alabama, Mobile, 1881, of Montgomery, Ala., died at the home of his daughter in Richmond, Ky., from locomotor ataxia, March 11, after an illness of seven years, aged 56.

P. W. Blakeley, M.D. (Years of Practice, Illinois), 1878, for nearly twenty years a practitioner of Galatia, Ill., died at his home in Marion, Ill., March 4, from lung disease, after an illness of several months.

Charles W. Townsend, M.D., New York Homeopathic College and Hospital, New York City, 1893, of New York City, died from brain abscess at the Hahnemann Hospital, New York City, March 7, aged 37.

John W. Cooper, M.D., Hahnemann Medical College, Philadelphia, 1884, health officer for Cecil County, Md., died at his home in Elkton, Md., March 10, from nephritis, after an illness of several years, aged 56.

O. C. Gilliland, M.D., Medical Department of Columbian University, Washington, D. C., 1894, died at his home in Washington, March 1, from disease of the lungs, after an illness of more than a year, aged 36.

John Benjamin Humphrey, M.D., Kansas City Homeopathic Medical College, 1897, died in Colorado City, Colo., January 1, from tubercular meningitis, after an illness of twenty-one months, aged 36.

R. H. Darling, M.D., College of Physicians and Surgeons, Keokuk, Iowa, 1882, of Crystal Falls, Mich., died in St. Agnes' Hospital, Fond du Lac, Wis., from brain tumor, March 7, after a long illness.

Lawrence J. Gerold, M.D., Baltimore Medical College, 1901, assistant surgeon at the State Soldiers' Home Hospital, Bath, N. Y., died at that institution, March 15, from heart disease, aged 41.

Henry J. Fortlage, M.D., University of Bonn, Germany, 1884, a charter member of the Cleveland Academy of Medicine, died at his home in that city, March 8, after a protracted illness, aged 48.

Cassander Paddock, M.D., Bennett College of Eclectic Medicine and Surgery, Chicago, 1875, died at his home in Fresno, Cal., from cancer, after an illness of nearly two years, aged 56.

Jewett Williams, Jr., M.D., Detroit College of Medicine, 1890, died at his home in Adrian, Mich., March 9, from osteosarcoma of the pelvis, after an illness of nearly five months, aged 42.

Francois Xavier Perrault, M.D., Ecole de Medecine et de Chirurgie, Montreal, 1850, formerly superintendent of the St. Jean de Dieu Insane Hospital at Longue Pointe, Quebec, died March 6, at the Hotel Dieu, Montreal, after an illness of two weeks, aged 80.

A. D. Axtell, M.D., Columbus (Ohio) Medical College, 1854, of Youngsville, Pa., died at the State Hospital, North Warren, Pa., January 29, after an illness of two years, aged about 80.

Donald Kennedy, M.D., Kentucky School of Medicine, Louisville, 1894, formerly of Shelbyville, Ind., died recently from consumption in Denver, Colo., after an illness of five years.

Hugh Nelson, M.D., Washington University School of Medicine, Baltimore, 1867, died at his home in Minneapolis from disease of the liver, after an illness of two weeks, aged 63.

Charles Edward Prentiss, M.D., University of Georgetown, Medical Department, Washington, D. C., for many years assistant librarian of Middlebury (Vt.) College, died recently.

John L. Hebron, M.D., Tulane University of Louisiana, Medical Department, New Orleans, 1853, died at his home in Hot Springs, Ark., March 8, from angina pectoris, aged 73.

C. W. Higgins, M.D., Starling Medical College, Columbus, 1865, died at his home in Derby, Ohio, March 8, from cerebral hemorrhage, after an illness of five months, aged 69.

Hannah Christiana Golden, M.D., State University of Iowa, College of Homeopathic Medicine, Iowa City, 1882, died at her home in Vinton, Iowa, March 6, after a long illness.

Edward W. Derby, M.D., New York University, New York City, 1853, for more than fifty years a practitioner of New York City, died at his home, March 10, aged 77.

Emil Luck, M.D., Dartmouth Medical School, Hanover, N. H., 1885, died at his home in Paterson, N. J., March 8, from chronic nephritis, after a long illness, aged 37.

Cassius W. Brooks, M.D., University of Vermont, Medical Department, Burlington, 1870, died recently at his home in Enterprise, Kan., and was buried March 10.

Adam K. Leberknight, M.D., Jefferson Medical College of Philadelphia, 1878, died at his home in Orristown, Pa., March 4, after an illness of six months, aged 55.

Rush M. Brown, M.D., College of Physicians and Surgeons in the City of New York, 1882, died at his home in Cordele, Ga., January 11, after a long illness, aged 48.

James A. O'Malley, M.D., New York University, New York City, 1887, died at his home in Pittston, Pa., from pneumonia, after an illness of two weeks, aged 43.

William H. Loomis, M.D., Hahnemann Medical College and Hospital, Chicago, 1876, of San Francisco, Cal., died at his home in East Oakland, Cal., February 9.

W. J. Pyland, M.D., Vanderbilt University, Medical Department, Nashville, 1867, died at his home in Wimberley, Texas, March 4, after a lingering illness.

Nicholas J. Dorsey, M.D., University of Maryland School of Medicine, 1847, for many years a practitioner of Chicago, died in Joliet, Ill., March 11, aged 84.

William Gordon Niles, M.D., Jefferson Medical College, Philadelphia, 1904, died from pneumonia in the Presbyterian Hospital, Philadelphia, March 16.

Thomas W. Bortree, M.D., Jefferson Medical College, Philadelphia, 1889, died at his home in Winwood, Pa., March 4, from heart disease, aged 46.

Frank J. Freel, M.D., Long Island College Hospital, Brooklyn, N. Y., died from pneumonia at his home in Stony Creek, Conn., March 9, aged 47.

Robert W. Duncan, M.D., University of Louisville, Medical Department, 1876, died recently at his home in White Mills, Ky., from paralysis.

Frederick C. Hennessy, M.D., Bellevue Hospital Medical College, New York City, 1897, died recently at his home in San Diego, Cal.

Francis H. Whittitt, M.D., College of Physicians and Surgeons, San Francisco, 1897, died recently at his home in Kernville, Cal.

J. Edgar Shepard, M.D., Missouri Medical College, St. Louis, 1883, died from heart disease at his home in Skidmore, Mo., March 4.

Lewis M. Webb, M.D., St. Louis Medical College, 1872, of Ewing, Ill., died at his home in that city, March 9, aged 59.

Queries and Minor Notes

MEDICINES CONTAINING ALCOHOL—SODIUM CHLORID ELIMINATION—SODIUM CACODYLATE IN CHOREA.

PLAINES, KANS., March 7, 1906.

To the Editor:—1. Can you give me any information pertaining to the sales of "patent" and proprietary medicines containing a certain percentage of alcohol, as I understand that the ruling of the Department of Internal Revenue will go into effect about April 1. I wish to know what medicines it will include.

2. What drugs will rid the system of hyper-sodium chloridia either chemically or mechanically, as advocated in certain forms of nephritis and epilepsy?

3. Has sodium cacodylate ever been advocated in treatment of chorea?

G. A. NICKELSON, M.D.

ANSWER.—1. The following preparations will be affected by the ruling referred to: Atwood's La Grippe Specific, Cuban Ginger, DeWitt's Stomach Bitters, Dr. Bowyer's Buchu Gin, Dr. Fowler's Meat and Malt, Duffy's Malt Whiskey, Gilbert's Rejuvenating Iron and Herb Juice, Hostetter's Stomach Bitters, Kudros, Peruna, Rock-candy Cough Cure.

2. There is no drug that will reduce the chlorid of sodium in the blood and urine, as the chlorid content of the blood and urine is dependent exclusively on the sodium chlorid or the hydrochloric acid given by mouth. Practical measures, therefore, for restricting the sodium chlorid excretion are to restrict the use of table salt to a minimum and not to give any hydrochloric acid as a stomachic. In epilepsy, a very good plan, and one that is commonly adopted, is to replace the sodium chlorid by sodium bromid. This can conveniently be done by placing a saltcellar containing sodium bromid at the disposal of the epileptic patient. The substitution of sodium bromid for sodium chlorid answers a double purpose. In the first place, it withholds sodium chlorid, and, in the second place, the bromin seems to facilitate the excretion through the bowel and the urine of accumulated sodium chlorid.

3. Cacodylate of soda is presumably the best symptomatic remedy for the treatment of chorea. It should be given in large doses, hypodermically. A very good mode of administering it is to inject half a Pravaz syringe full of a solution containing half a grain to the ounce, every four hours until the choreiform movements stop. Astonishing results are frequently witnessed within 24 hours. Effects of arsenic poisoning rarely become manifest. The attention should be called to the fact that the breath will assume a very strong odor of garlic very soon after the administration of the first dose.

CONTRACT PRACTICE.

KANKAKEE, ILL., March 19, 1906.

To the Editor:—In THE JOURNAL, March 17, page 824, I note communication by Dr. G. E. Holtzapple, York, Pa., and as a partial answer to his questions and acting on your suggestion, I submit the action taken by the Kankakee Physicians' Club in such matter. The following resolutions are self explanatory:

Resolved, That on and after the date of the passage of this resolution no member of this society shall accept the position of club, society or organization, company or corporation physician, or agree to continue to do any medical or surgical work for any club, society or organization, company or corporation, at a less rate than the regular or customary charges for like services rendered by other physicians, members of this club, for patients not members of such club, society or organization, company or corporation, and also that in no case shall any physicians agree to attend the families of the members of such club, society or organization, company or corporation at a less price than the regular rate of fee as fixed by this club.

Provided, however, that nothing in this resolution shall be construed as preventing any member of this club from attending the worthy poor at a less rate or rendering free service if necessary in such cases.

Any violation of this agreement shall be considered unprofessional conduct, and the punishment of any member violating the provisions of this act shall be fixed by the club.

Resolved, That no physician of this club make an examination for life insurance companies for a less fee than:

For \$1,000 or less	\$2.00
Over \$1,000	5.00
Over \$5,000	10.00

Adopted, Feb. 16, 1906.

A. L. GAGNON, Secretary.

IS INSOMNIA EVER FATAL?

ELIST, MICH., March 5, 1906.

To the Editor: Do you know of any cases that have ever been recorded in medical literature of persons whose death was caused directly by loss of sleep? Such cases are very rare, and on that account, if any have ever been recorded, one ought to be able to find some account of them. Where would one be most liable to find any literature on the subject?

R. W. RUTHERFORD, M.D.

ANSWER.—It would probably be hard to find a reported case of death from sleeplessness absolutely exclusive of all contributing factors. The causes that would prevent sleep would themselves be destructive of life, if continued. It would also be difficult to say that a case of insomnia was absolute. Men have been known to

sleep under the most unfavorable conditions, and, it is said, even in the briefest intervals of torture. Apparent sleeplessness, moreover, may exist to a very large extent, in some cases in some forms of insanity, especially the so-called circular type. Patients have been known to go apparently without sleep for days and even weeks at a time without any serious physical consequences. They probably did sleep some, but it could hardly be detected. The amount of sleep required varies greatly with the individual, and it is claimed that some distinguished men have lived for considerable periods with one, two or three hours' sleep out of the twenty-four. These cases, however, were not under conditions satisfactory for physiologic experiments. It has been said that the Chinese have a punishment for criminals which consists in depriving them of sleep until death comes to their relief, but there are no scientific observations of such cases, as far as we are aware, and it would be hard to prevent the means used to cause insomnia from themselves contributing to the fatal result. It can be safely said that there are no recorded satisfactory observations of fatal absolute insomnia.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending March 17, 1906.

Davis, Wm. B., deputy surgeon-general, relieved from duty as chief surgeon, Department of the Columbia, and will proceed to New York City, N. Y., for temporary duty at Medical Supply Depot.

Wolfe, Edwin P., Shockley, M. A. W., Shaw, Herbert G., and Halsell, H. S., asst.-surgeons, relieved from duty in the Philippines Division and ordered to proceed to San Francisco, and on arrival to report by telegraph to the military secretary of the Army for further orders.

Egan, Peter R., surgeon, ordered to report in person to Major General James F. Wade, U. S. Army, president of an Army retiring board at Governors' Island, N. Y., for examination by the board, and on completion of his examination will return to station, Fort Hamilton, N. Y.

Woodson, Robert S., surgeon, leave of absence extended 10 days. Keeder, Frank R., surgeon, reports on 30 days' leave of absence from date, March 12, 1906.

Davis, William T., asst.-surgeon, on arrival in the United States, will proceed without delay to Washington Barracks, D. C., and report to the commanding officer of the General Hospital at that post for duty with Company "A," Hospital Corps.

Torney, Geo. H., deputy surgeon-general, in addition to his present duties, will, on the retirement of Col. John D. Hall, asst.-surgeon-general, report to the commanding general, Department of California, for duty as chief surgeon of that department, and also assume the duties of Medical Superintendent, Army Transport Service, at San Francisco.

Lafayette, Louis A., Ebert, Rudolph G., Purviance, Wm. E., surgeons, appointed members of a board of medical officers to meet at the call of the president thereof, at Manila, P. I., for the examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion or advancement. Keeder, Frank R., surgeon, will report in person on Tuesday, May 8, 1906, to Major Louis A. La Garde, surgeon, president of examining board, Manila, P. I., for examination to determine their fitness for advancement: McAndrew, P. H., first lieutenant; Van Poede, G. M. D., first lieutenant; Gies, Geo. H. R., first lieutenant; Van Dusen, James W., first lieutenant; De Witt, Wallace, first lieutenant; Thornburgh, R. M., first lieutenant; Grubbs, R. B., first lieutenant; Shortridge, E. D., first lieutenant; Field, Peter C., first lieutenant; Shaw, Herbert G., first lieutenant.

Keeder, Frank R., surgeon, the leave of absence granted in S. O. 30, Department of California, c. s., for 30 days, is extended one month.

Davis, Will L., asst.-surgeon, left Jefferson Barracks, Mo., with recruits en route to Presidio of San Francisco.

Hallock, H. M., surgeon, sick leave extended 30 days.

Whinnery, Jean C., dental surgeon, ordered from Fort Stevens, Ore., to duty at Fort Columbia, Wash.

Casaday, George H., dental surgeon, ordered, on arrival at San Francisco, to duty at the Army General Hospital, Presidio of San Francisco.

Stone, Frank P., dental surgeon, relieved from duty at the Army General Hospital, Presidio of San Francisco, and ordered to duty at Fort Sam Houston, Texas.

Lauderdale, Clarence E., dental surgeon, relieved from duty at Fort Sam Houston, Texas, and ordered to Manila, P. I., for duty in the Philippine Division.

Rhodes, Rex H., dental surgeon, relieved from duty in the Philippines Division, and ordered to the United States on the first transport after May 3, 1906.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending March 17, 1906.

Dunn, H. A., P., asst. surgeon, detached from the naval proving ground, Indian Head, Md., and ordered to the *Princeton*.

Shaw, Herbert G., asst.-surgeon, detached from the *Princeton* and Baker, M. W., P., asst.-surgeon, detached from the Naval Hospital, Washington, D. C., and ordered to the Naval Hospital, New York, N. Y.

Chandrasekar, F. B., acting asst.-surgeon, ordered to the Naval Hospital, Washington, D. C.

Langhorne, C. D., surgeon, detached from the *Denver* and ordered home to wait orders.

Lumsden, G. P., surgeon, detached from the *Olympia*, when put out of commission, and ordered to the *Minneapolis*.

Norton, O. D., surgeon, detached from the *Minneapolis* and ordered home to wait orders.

Plummer, R. W., P. A. surgeon, detached from the naval sub-recruiting station, St. Joseph, Mo., and ordered to the *Denver*.
 Smith, W. B., asst. surgeon, detached from the *Olympia*, when put out of commission, and ordered to the *Harcock*.
 Cone, I. F., and Flint, J., asst. surgeons, appointed assistant surgeons, with rank of lieutenant, junior grade, from February 28, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ending March 14, 1906:

Wickes, H. W., P. A. surgeon, granted leave of absence for two days, from March 10, 1906.
 King, W. W., P. A. surgeon, granted leave of absence for one month, from March 12, 1906.
 Goldberger, Joseph, P. A. surgeon, granted leave of absence for twenty-one days, from April 11, 1906.
 Amesse, J. W., P. A. surgeon, directed to proceed from Ellis Island, N. Y., to New Orleans, for special temporary duty in the State of Louisiana.
 Burkhalter, J. T., P. A. surgeon, granted extension of leave of absence for ten days from March 2, 1906.
 Boggers, J. S., asst. surgeon, granted three days' leave from March 12, 1906.
 Wacker, W. S., asst. surgeon, relieved from temporary duty at Vineyard Haven, Mass., and directed to proceed to New Orleans, for special temporary duty in the State of Louisiana.
 Smith, F. C., asst. surgeon, directed to proceed from Detroit to New Orleans, for special temporary duty in the State of Louisiana.
 Goldsborough, B. W., acting asst. surgeon, granted two days' leave of absence, from March 14, 1906.
 Richardson, N. D., acting asst. surgeon, granted leave of absence for thirty days, from March 7, 1906.
 Stephenson, Chas. W., Pharmacist, granted leave of absence for thirty days, from March 12, 1906.

BOARDS CONVENED.

A board of medical officers was to meet at the Bureau, Washington, D. C., April 2, 1906, to determine the fitness for promotion to the grade of surgeon of certain passed assistant surgeons. Detail for the board: Assistant Surgeon-General W. J. Pettis, chairman; Assistant Surgeon-General J. M. Easer and Surgeon L. L. Williams, recorder.

A board of medical officers was to meet at Mobile, Ala., March 17, 1906, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: P. A. Surgeon Edward Francis, chairman; Acting Assistant Surgeon A. S. Taylor, recorder.

A board of medical officers was to meet at Chicago, March 13, 1906, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: P. A. Surgeon G. B. Young, chairman; P. A. Surgeon S. B. Grubbs, recorder.

A board of medical officers was to meet at the Bureau, Washington, D. C., March 15, 1906, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Assistant Surgeon-General J. W. Kerr, chairman; Assistant Surgeon J. W. Trask, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 16, 1906.

SMALLPOX—UNITED STATES

California: Los Angeles, Feb. 24-March 3, 5 cases; San Francisco, 6 cases, 1 death.
 Delaware: Wilmington, March 3-10, 1 case.
 Florida: Jacksonville, Feb. 24-March 10, 17 cases.
 Georgia: Augusta, March 5-12, 1 case.
 Louisiana: New Orleans, March 3-10, 20 cases.
 Maryland: Baltimore, March 3-10, 6 cases.
 Massachusetts: Somerville, March 3-10, 1 case.
 Michigan: Detroit, March 3-10, 3 cases.
 Mississippi: Natchez, Feb. 24-March 3, 2 cases.
 Missouri: St. Louis, March 3-10, 4 cases.
 North Dakota: Grand Forks County, Jan. 1-31, 1 case; McHenry County, 29 cases; Nelson County, 6 cases; Ward County, 1 case.
 Ohio: Cincinnati, Feb. 24-March 3, 10 cases.
 Tennessee: Memphis, Feb. 24-March 3, 3 cases; Nashville, March 3-10, 1 case.
 Utah: Salt Lake City, Feb. 24-March 3, 16 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, Jan. 21-Feb. 11, 13 cases, 3 deaths.
 China: Hongkong, Jan. 27-Feb. 3, 2 cases, 2 deaths.
 Ecuador: Guayaquil, Feb. 1-18, 17 deaths.
 France: Paris, Feb. 17-24, 9 cases, 1 death.
 Great Britain: Bristol, Feb. 17-24, 1 case; Leeds, Feb. 19-26, 1 case.
 India: Bombay, Feb. 6-13, 9 deaths; Calcutta, Jan. 27-Feb. 3, 143 deaths; Karachi, Feb. 4-11, 12 cases, 1 death; Madras, Feb. 3-9, 22 deaths; Rangoon, Jan. 27-Feb. 3, 40 deaths.
 Italy: General, Feb. 8-22, 40 cases.
 Netherlands: The Rotterdam, Jan. 17-24, 1 case.
 Russia: Moscow, Feb. 3-10, 16 cases, 2 deaths; Odessa, Feb. 10-17, 3 cases; 3 deaths; St. Petersburg, March 3-17, 15 cases, 2 deaths.
 Spain: Barcelona, Feb. 10-20, 8 deaths.
 Turkey: Alexandretta, Feb. 10-17, 20 cases, 4 deaths.

YELLOW FEVER—FOREIGN

Brazil: Rio de Janeiro, Jan. 21-Feb. 11, 19 cases, 6 deaths.
 Ecuador: Guayaquil, Feb. 1-18, 17 deaths.
 Honduras: Puerto Cortes, March 13, 1 case.
 Mexico: Merida, Feb. 18-24, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Manila, Jan. 6-20, 4 cases, 4 deaths; Provincias, 336 cases, 249 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Jan. 27-Feb. 3, 57 deaths; Rangoon, 2 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Jan. 6-20, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Jan. 21-Feb. 11, 16 cases, 3 deaths.
 China: Hongkong, Jan. 27-Feb. 3, 5 cases, 5 deaths.
 India: Bombay, Feb. 6-13, 124 deaths; Calcutta, Jan. 27-Feb. 3, 31 deaths; Karachi, Feb. 4-11, 9 cases, 6 deaths; Madras, Feb. 3-9, 13 deaths; Rangoon, Jan. 27-Feb. 3, 25 deaths.
 Peru: Callao, Jan. 26-Feb. 12, 1 case; Chicama Valley, Feb. 14-21, 1 case; Chilcayo, Jan. 26-Feb. 12, 5 cases, 1 death; Chocisca, 3 cases, 2 deaths; Manacu, Feb. 14-21, present; Moche, 1 case; Mollendo, Jan. 26-Feb. 12, 4 cases, 3 deaths; Trujillo, 16 cases, 10 deaths.

Book Notices

URIC ACID. The Chemistry, Physiology and Pathology of Uric Acid and the Physiologically Important Purin Bodies, with a discussion of the Metabolism in Gout. By F. H. McGruddau. Paper, pp. 318. Price, \$2.50 net. Cloth, \$3.00 net. New York: Paul B. Hoeber.

This little volume from the laboratory of physiology and chemistry of the Harvard Medical school, constitutes the most complete literary review of the uric acid question that so far has been published. The pure chemistry of uric acid and of the whole group of purin bodies, the solubility of uric acid and the urates, the physiology of uric acid, including its formation and decomposition in the body, the effects of drugs on the excretion and solubility of uric acid, and finally, its pathology and metabolism in gout and lithemia, are all very carefully discussed. The facts collected, therefore, represent practically all that is known in regard to the uric acid subject, and the author deserves immense credit for his diligent search through innumerable publications for the material that forms the basis of his book.

The conclusions that the author draws from his collected data, including some experiments of his own, are, on the whole, sound. His avowed purpose is to rely on the arrangement of the facts themselves to bring out the explanation of the phenomena. This is a good plan, so far as it goes, but, unfortunately, the large and valuable field of clinical experience, or what may be called empiricism, especially in regard to the therapeutics of uric acid disorders, is not sufficiently included in the calculation. While we agree with the author that "rheumatic diseases and uric acid metabolism do not at the present time seem to be closely related," and while we endorse heartily his severe arraignment of Haig's theories and the many fallacies and inconsistencies inherent in the irrational use of many so-called uric acid remedies, we nevertheless can not without qualification endorse the statement that "the facts of chemistry and physiology do not furnish any scientific evidence for the alkali therapeutics of gout," nor can we agree with him when he says that uric acid is not an antecedent of uric in the destructive metabolism of proteins; for it most assuredly is at least one of the intermediary bodies between albumin and uric.

Particularly valuable is the chapter on the uric acid solvents; for the author shows most conclusively that most of them, in the very nature of things, are inert and useless. First, because uric acid can not be accused of producing the protean array of symptoms summarized under the name of uric acid diathesis, and, second, because these various remedies could not exercise appreciable effect either on the uric acid excretion or its precipitation in the tissues, even if uric acid were the *fons et origo malorum*.

The book is an exceedingly useful volume for both reference and connected reading; it is critical, but just, and should help clear up the mist of theory and false conceptions that obscure so densely our understanding of uric acid metabolism and of its significance, or better, lack of significance, in pathogenesis.

GALVANIC, FARADIC AND SINUSOIDAL APPARATUS. Pp. 122. Illustrated. For free distribution. Chicago: R. V. Wagner Company, 1906.

This is practically a catalogue, but besides a list of apparatus it contains much information of value to physicians interested in electrotherapeutics, information that evidently is furnished by one who thoroughly understands the subjects.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS, including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, Minute Directions for Prescription Writing and Avoiding Incompatibility, also the Antidotal and Antagonistic Treatment of Poisoning. By S. O. L. Potter, A.M., M.D., M.R.C.P. Tenth Edition. Revised and in greater part rewritten. Cloth. 75 pp. 241. Price, \$5.00 net. Philadelphia: P. Blakiston's Son & Co., 1906.

This edition has been largely rewritten to conform to the new Pharmacopœia; new matter articles have been added and material considered obsolete or of slight importance has been omitted. The new matter includes a list of incompatibles for each drug, as well as descriptions of many comparatively new drugs, chiefly synthetics, which makes the book more valuable for practicing physicians. The articles on acetonitrid, acetphenetidin, acids, alkalies, animal extracts and several standard drugs have been rewritten. The general arrangement of the subjects is the same as in previous editions.

A. MANUAL OF MATERIA MEDICA AND PHARMACOLOGY, comprising all Organic and Inorganic Drugs which are or have been official in the United States Pharmacopœia, together with Important Allied Species and Useful Synthetics. Especially Designed for Students of Pharmacy and Medicine, as well as for Druggists, Pharmacists and Physicians. By D. M. R. Culbreth, Ph.D., M.D. Fourth Edition, Enlarged and Revised, with 487 Illustrations. Cloth. 1p. 976. Price, \$4.75. Philadelphia: Lea Brothers & Co., 1906.

The popularity of Professor Culbreth's work is evidenced by the fact that four editions of the book have appeared within the last nine years. As a compendium of materia medica and pharmacology it will be found most useful to the student, both of pharmacology and of medicine, as well as to the practicing pharmacist or physician. It is concise and comprehensive and can be commended to physicians who desire a work of this character.

MEMORANDA ON POISONS. By T. H. Tanner, M.D., F.R.S., Tenth Revised Edition. By H. Leftmann, A.M., M.D. Cloth. 1p. 177. Price, 75c. Philadelphia: P. Blakiston's Son & Co., 1905.

New matter has been inserted in this edition of Tanner's manual without materially increasing the size of the book, which is convenient for carrying in the pocket. The subjects of general toxicology, corrosive poisons, simple irritants, specific irritants and neurotic poisons, including narcotics, anesthetics, intoxicants and drugs producing delirium, convulsions, paralysis and asphyxia are considered and the antidotes given.

State Boards of Registration

COMING EXAMINATIONS.

UTAH State Board of Medical Examiners, Salt Lake City, April 2. Secretary, R. W. Fisher, Salt Lake City.

ARIZONA Board of Medical Examiners, Phoenix, April 2-3. Secretary, Anell Martin, Phoenix.

CALIFORNIA Board of Medical Examiners, San Francisco, April 2-3. Secretary, Charles L. Tisdale, San Francisco.

IDAHO State Board of Medical Examiners, Pocatello, April 3. Secretary, J. D. Conant, Jr., Genesee.

MONTANA Board of Medical Examiners, Senate Chamber, the Capitol, Helena, April 3. Secretary, William C. Kiddell, Helena.

NORTH DAKOTA State Medical Examining Board, Grand Forks, April 3. Secretary, H. M. Wheeler, Grand Forks.

OHIO Board of Registration and Examination, State House, Columbus, April 3. Secretary, D. N. Kinsman, Columbus.

MINNESOTA State Board of Medical Examiners, State Capitol Building, St. Paul, April 3-5. Secretary, O. E. Linjer, Minneapolis.

MISSOURI State Board of Health, Kansas City, April 3-5. Secretary, J. A. E. Adeock, Warrensburg.

RHODE ISLAND State Board of Health, State House, Providence, April 5. Secretary, Gardner T. Swarts, Providence.

GEORGIA Medical Examining Board (Regular), the Capitol, Atlanta, April 7. Secretary, E. R. Anthony, Griffin.

ARKANSAS State Board Medical Society, Little Rock, April 10. Secretary, J. P. Runyan, Little Rock.

MISSOURI State Board of Health, St. Louis, April 10-12. Secretary, J. A. B. Adeock, Warrensburg.

WEST VIRGINIA State Board of Health, Parkersburg, April 10-12. Secretary, H. A. Barlow, Paint Pleasant.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, D. C., April 12. Secretary, William C. Woodward, Washington, D. C.

ILLINOIS STATE BOARD OF HEALTH, Northwestern University Building, Chicago, April 18-20. Secretary, J. A. Egan, Springfield.

Arkansas Report Correction.—The report of the examination held at Little Rock, in January, 1906, in *THE JOURNAL*, Feb. 10, 1906, page 455, implies that a graduate of Tufts Medical

College and of the American Medical College failed. This applicant was a graduate of the American College of Medicine and Surgery, having attended Tufts for three years and the college from which he graduated for one year.

Nebraska February Report.—Dr. George H. Brash, secretary of the Nebraska State Board of Health, reports the written examination held at Lincoln, Feb. 7-8, 1906. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 8, of whom 3 passed and 5 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
College of P. and S., Chicago	(1905)	77.1
Barnes Med. Coll.	(1905)	75.
Eclectic Med. Inst., Cincinnati	(1872)	89.2
FAILED.			
University of Nebraska	(1905)	61.1, 62.7, 72.7
Central Med. Coll., St. Joseph	(1905)	64.3
Kansas City Homeo. Med. Coll.	(1904)	68.2

Pennsylvania Medical Examiners Appointed.—Governor Pennypacker has appointed the following men members of the State Medical Examining Board: Dr. Francis R. Packard, Philadelphia, editor of the *American Journal of Medical Sciences*, is appointed to take the place of the late Dr. Hiram McConnell, New Brighton. Dr. Henry Beates, Jr., Philadelphia, was reappointed. Dr. W. O. Koffer, Altoona, and Dr. S. J. H. Louthier, Somerset, were appointed in the places of Dr. C. W. Ewing, Harrisburg, and Dr. L. P. O'Neal, Mechanicsburg.—The following men were appointed by Governor Pennypacker on the Homeopathic Medical Examining Board: Gustave A. Mueller, Allegheny; C. S. Middleton, Philadelphia; H. M. Bunting, Norristown.

Pennsylvania December Report.—The State Medical Society of Pennsylvania reports the written examination, held at Philadelphia and Pittsburg, Dec. 12-15, 1905. The total number of applicants examined was 107, of whom 77 passed and 30 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Jefferson Med. Coll. (1904)	75, 80.9, 86.2;	(1905)	76.5, 78.5
78.7, 79.7, 81.2, 81.8, 82.7, 84.3, 85.1.			
Medico-Chirurgical Coll., Philadelphia, (1898)	80.5, 80.7, 81.2, 82.9;	(1904)	75, 75.4, 77.8, 78.2,
(1905)	82.9;	(1904)	75;
(1905)	79.7;	(1904)	77.4, 77.8, 78.2,
78.9, 80.7, 82.8;			
Wanam's Med. Coll., Philadelphia	(1903)	80;
(1905)	78		
Howard University	(1904)	80.5;
(1905)	75.5		
University of Edinburgh	(1904)	81.5;

* Year of graduation not given.

Pennsylvania Homeopathic Report for December.—The Homeopathic Medical Society of Pennsylvania reports the written examination held at Philadelphia, Dec. 12-15, 1905.

The total number of applicants examined was 10, all of whom passed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Hahnemann Med. Coll., Philadelphia (1903)	80.8	(1904)	88.5
(1905)	75.4, 75.8, 77.2, 78.4, 87.7.		
University of Wooster	(1893)		82.4
Eastern University	(1902)		83.8
New York Homeo. Med. Coll.	(1899)		95.4

Pennsylvania Eclectic Report for December.—The Eclectic Medical Society of Pennsylvania reports the written examination held at Harrisburg, Dec. 12-15, 1905. The total number of applicants examined was 8, all of whom passed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Maryland Med. Coll.	(1905)		88.4
Royal University, Palermo	(1898)		75.
American Coll. of Med. and Surg.	(1903)		88.1
University of the South	(1899)		78.3
College of P. and S., Baltimore	(1904)		84.9
Western Pennsylvania Med. Coll.	(1906)		82.3
University of Modena, Italy	(1903)		78.0
University of Naples, Italy	(1894)		78.8

Utah January Report.—Dr. R. W. Fisher, secretary of the State Board of Medical Examiners of Utah, reports the written examination held at Salt Lake City, January, 1906. The number of subjects examined was 19; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 3, all of whom passed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Michigan	(1904)		79.7
Marion-Sims Beumont Med. Coll.	(1904)		76.2
Jefferson Med. Coll.	(1904)		84.2

* Second examination.

Virginia, New Board of Medical Examiners.—The governor has appointed the following members of the State Board of Medical Examiners to serve for four years: Drs. Willard B. Robinson, Tappahannock; Herbert M. Nash, Norfolk; Junius E. Warriner, Brook Hill; William W. Wilkinson, La Crosse; Richard S. Martin, Stuart; Samuel Lile, Lynchburg; Robert C. Randolph, Boyce; Robert M. Slaughter, Theological Seminary; Elliott T. Brady, Abingdon, and Charles W. Rodgers, Staunton; and state at large, Drs. Rawley W. Martin, Lynchburg; A. S. Pridly, Bristol, and R. Bruce James, Danville.

- Medical and Chirurgical Faculty of Maryland, Baltimore, April 24-26.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Regular Meeting of the Section on General Medicine, held Feb. 12, 1906.

DR. WILLIAM E. HUGHES in the Chair.

Chronic Valvular Disease.

DR. FREDERICK J. KALTHER exhibited a patient whose case was interesting on account of the sudden onset of the symptoms, the very loud diastolic murmur which could be heard over the entire trunk and often three feet away from the body, and the very slight arterial phenomena. Following the ingestion of a large quantity of beer one of the heart valves ruptured.

DISCUSSION.

DR. J. ALISON SCOTT said that it was unusual for rupture of a valve to occur, except under great muscular strain. In this case the increased blood tension probably was produced by the alcohol.

DR. JAMES M. ANDERS said that rupture of normal heart valves was not frequent, and that it would be interesting to know whether or not the man had had a previous valvular lesion. Under those circumstances rupture would be more likely to occur, and in two instances in his experience had occurred, on slight muscular exertion.

DR. WILLIAM E. ROBERTSON said that in his experiments in the taking of blood pressure he had found that a good dose of alcohol would bring about a lowering of the blood pressure. In one instance in which the blood pressure was 115 it fell to 95 in twenty minutes after the giving of an ounce and a half of alcohol. He thought it possible that in this instance the enormous amount of fluid taken would increase the blood pressure and in that way throw extra work on the heart. In myocardial conditions the blood pressure is often very high when it would be supposed to be low. He believes that some other factor than the muscular pressure itself accounts for these variations in tension. This he thinks is explained by the retention of poisons in the system which have a vaso-constrictive effect.

Hysterical Neuroses of the Stomach.

DR. J. HENDRIE LLOYD exhibited a patient with a rare and curious hysterical condition of the stomach and abdomen. It was somewhat like the disease noted by French authors called "Rhythmical Borborygmi." The patient, who was hysterical, has a loud rumbling to and fro sound in the abdomen, probably caused by the passage of air to and fro either in the stomach or transverse colon, and this is produced by a rhythmical movement of the abdominal muscles. The condition came on during convalescence from typhoid; was unattended by pain, nausea or any evidence of organic disease. Dr. Lloyd reviewed briefly some of the more important and rare hysterical conditions of the abdominal organs, among which especially were anorexia nervosa and hysterical myocymia, or chewing of the end in the human subject, a condition which has been observed especially in neurotics, as in insane patients, idiotic and epileptic children, etc., and also in neurasthenics. Among other diseases referred to was phantom tumors, false pregnancies, so called, all of which are seen sometimes in hysterical subjects. The paper emphasized the fact that there is still a wide field for the purely medical clinician in diseases of the stomach, all of which diseases the physician is not yet ready to resign to the surgeon.

DISCUSSION.

DR. JAMES M. ANDERS believed the case could not be anything else than a neurosis. Tending to this opinion were the facts of the typically hysterical appearance of the patient, and that when breathing and the motion of the diaphragm were arrested the noise ceased. It was evidently not due, therefore, to an independent peristaltic action of the stomach. That the diaphragm should make the peculiar noise in a normal stomach was difficult of explanation. An hour-glass contraction of the stomach was suggested as an explanation. It was thought possible that the diaphragm in forcing air and fluid through a narrow opening caused some noise; and, naturally, with retraction of the diaphragm and relaxation of the stomach there would be a regurgitation into the cardiac end.

DR. J. ALISON SCOTT thought that from the character of the noise there must be both air and fluid concerned in the noise. He suggested the existence of a partial obstruction at the pyloric end of the stomach, or along the curvature of the stomach. He thought either possibility could be easily demonstrated by an inflation of the stomach.

DR. A. O. J. KELLY said the case appeared to be some stomach condition in a hysterical subject. He referred to a patient who had been subjected to abdominal operations and had, following the third, developed a stomach condition manifested by air regurgitation, and vomiting coming on two, three or more times daily. She had been under various treatments and ultimately was operated on on the supposition of the presence of adhesions near the pylorus. These were found, and with their removal the regurgitation of food ceased promptly.

DR. S. SOLIS-COHEN thought that there seemed to be a large hysterical element in association with the respiratory tract rather than with the stomach. He thought it would be of

interest to know whether with the passage of the stomach tube there was any escape of gas. In an hour-glass stomach which he had seen there had been contraction in an unusual direction, and he wondered whether there could be such a condition in the present case. Personally, he did not believe the condition was a surgical one, although he was open to conviction in that direction if the skiagraph should show a lesion.

DR. WILLIAM E. HUGHES said that he had occasionally seen, and especially in neurotics, stomachs whose esophageal opening was normally placed, whose pylorus was where it ought to be, and yet, without any actual increase in the size of the stomach, the lower border was almost down in the pelvis, necessitating a short, sharp bending of the stomach on itself. He thinks it possible that the motion occasioned by the sharply descending diaphragm might be enough to produce such a sound.

In any of the hysterical conditions there should be considered the possibility of cure by operation, and in connection with this two elements must be borne in mind—a hysterical basis and an acquired habit. If by operation the habit can be broken up, the hysteria is at least cured temporarily. A fact too often lost sight of is that there is an anatomic or pathologic basis for hysterical manifestations, such as there was in Dr. Kelly's case. In a certain number of gastric cases there is absolutely no neurosis. A case in point is that of a man over 80 years of age who had for many years regurgitated his food. He was entirely free from neurosis, and in his case the condition was purely the result of habit.

Pulmonary Abscess.

DR. JAMES M. ANDERS and DR. GEORGE E. PFAHLER presented a man, aged 28, married, an engineer, whose present illness began as typical typhoid fever, the temperature throughout, however, pursuing an intermittent type. At the end of the third week phlebitis affecting the left femoral vein developed and subsided that week. Then a bronchopneumonia appeared and after running its course, the patient developed a lobar pneumonia. Physical examination revealed an area of muffled tympany and cavernous breathing at the angle of the right scapula posteriorly. The abscess cavity attained its maximum size in about seventy-two hours. Three days later, while the patient was sitting up for an examination he developed a severe paroxysm of cough attended with the expectoration of about two ounces of yellow purulent sputum. A microscopic examination showed pus cells, elastic fibers, pneumococci and streptococci. The process was studied by radiograph while the patient was in the supine position and the exposure was made after inspiration. This showed an incomplete consolidation of the right lower lobe with a cavity in its upper portion about two inches in diameter, extending from the upper border of the fifth rib posteriorly to the middle of the second interspace in the mid-scapular line. About ten days later the radiograph showed less evidence of consolidation: the abscess cavity was still of the same size. Eleven days later the cavity was still visible, but was decreased to about its original size, while on the same side the diaphragm had risen to the lower border of the seventh rib. The fact that the diaphragm moved its position upward as compared with its normal position was considered indicative of Nature's process of assisting mechanically in closing an abscess cavity of the lungs. Operative interference had been seriously considered when the fortunate accident occurred leading to the discharge of the pus through a bronchus. After this the general and local symptoms steadily subsided until the necessity for operation no longer existed and convalescence was gradually established.

Recent Therapeutic Experiences with Pneumonia.

DR. S. SOLIS COHEN recently tested in a selected case the value of enormous doses of quinin in pneumonia. The patient was a young robust man admitted to the hospital shortly after his initial chill, still showing some crepitant rales, with bronchial breathing and temperature of about 103. Dr. Cohen gave him 15 grains of quinin every two hours, with the direction that it be continued until there was some sign of quinin poisoning. The man took 105 grains without effect, except a reduction of temperature. In the course of thirty-

six hours he was found to be in good condition, with the physical signs increased, but the fever gone. The pulse was very quiet, the breathing easy and the patient was feeling comfortable. The quinin was continued, in doses of about 50 grains a day, for two or three days, at the end of which time the physical signs began to show a beginning of resolution and the patient went on to recovery, without a crisis. There had been a gradual fall of temperature from 103 to normal.

Dr. Cohen also reported his results in the employment of colloidal silver in the treatment of endocarditis and in associated forms of sepsis. In a case of bronchopneumonia in a child, with pronounced meningeal symptoms, the remedy was used by the rectum and afterward applied in ointment over the neck, giving relief to the patient. In a case of lobar pneumonia following bronchopneumonia recovery took place. In that case also the symptomatic recovery preceded the disappearance of the physical signs. Dr. Cohen is convinced of the great value, in the treatment of pneumonia, of keeping the windows of the room in which the patient is sleeping open all the time, the bed being protected from the draft. An advantage in the administration of the colloidal silver is that as it is not given by the stomach, it need not interfere with other treatment.

Dr. Cohen does not know the action of the colloidal silver, but ventured the opinion that it renders the tissues less favorable as a culture medium, and that, to a degree, it favors the destruction of toxins. The dose usually employed by him by the rectum is from 2 to 5 grains; or the solution of from 2 to 5 grains in from one-half to 2 ounces of water. For intravenous use care should be taken to secure a specimen which has been well cared for by the apothecary. In pneumonia he has used the silver in suppositories containing 30 minims of a 2 per cent. solution.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Acute Catarrhal Conjunctivitis.

In the treatment of acute catarrhal conjunctivitis, according to J. H. Kincaid in *Southern Jour. of Med. and Surgery*, cleanliness is of the greatest importance. The eyes should be thoroughly cleansed every hour or even more frequently if much discharge is present. This should be done with a saturated solution of boric acid (4 per cent.).

Cold compresses applied locally are of service, unless a corneal ulcer is present. Especially is cold of value when there is much swelling of the lids. A small ice-bag may be used instead of the compresses. Kincaid states that some authors recommend silver nitrate in the strength of 2 to 5 grains (.12-.30) to the ounce (.30.), applied locally to the everted lids.

The eyes should never be bandaged, nor should poultices be applied to them. The patient should not be allowed to use the eyes and should wear dark glasses as a protection from the light, wind and dust. Temperate habits and proper hygiene must be insisted on by the physician.

Earache.

As soon as a patient complains of a severe earache, according to Bardsley in *Med. Record*, it must be realized that a septic process is present, which may reach a dangerous state if left unchecked. The patient, therefore, should be kept quiet, put to bed and placed on a liquid diet. The bowels must be kept freely open. Opium may be given, if necessary, to insure rest and comfort, but should be used with caution. Dry heat or an ice-bag should be applied to the ear. Heat, as a rule, is preferable to the patient. Every three hours the ear should be irrigated gently with a hot solution of bichlorid of mercury in strength of 1 to 5,000, followed by a few drops of a carbolic acid solution in glycerin instilled into the ear.

Bardes condemns the practice of applying an onion, an oil or a tincture to the external meatus, as being uncleanly and in many cases harmful. Under no circumstances should the patient be allowed to suffer longer than twenty-four hours; and if the pain continues and the drumhead is swollen, inflamed and distended, surgical procedures should be resorted to without delay. The drumhead should be thoroughly incised and treated in the same way as any other septic formation. When the tympanic membrane is incised freely and not simply punctured, instant relief is given the patient, dangerous complications are prevented and recovery is hastened. The author recommends a hypodermic injection of morphin or a whiff of chloroform or nitrous oxid, when the drum may be freely incised with but little pain. In all cases, symptoms of extension to the mastoid cells must be watched for. The symptoms of mastoid involvement are tenderness over the mastoid region and sagging of the posterior superior wall of the canal.

Edema of Glottis in Children.

The following combination is recommended by *Bul. gen. de Ther.* as a spray to relieve the edema of the glottis in children and infants:

R. Aluminis	
Acidi tannici, aa.	gr. xv
Ext. kramerie	3ss
Aque	3iiss
	105

M. Sig.: To be used in the atomizer as a spray to the throat five or six times a day.

Chapped Hands.

The following combination is recommended as a valuable local remedy in the treatment of chapped hands:

R. Sodii salicylatis	3i
Balsami peruviani	3iv
Glycerini	3ss
Aque rose	3vi
	180

M. Ft. lotio. Sig.: To be applied to the hands night and morning.

Hydrocyanic Acid.

Hydrocyanic acid is an old-time preparation, used as an antispasmodic in the various forms of reflex vomiting. It has also been used in many other conditions of nervous origin such as the cough due to disturbances of the heart and in asthma. It is a most efficient sedative to the gastric mucous membrane in such conditions as gastralgia, ulcer and carcinoma, and is regarded as a satisfactory sedative in cases of pruritus. Deasley recommends the following combinations containing dilute hydrocyanic acid:

In dry irritable coughs:	
R. Acidi hydrocyanici dil.	m. iii
Vini ipecacuanhæ.	m. v
Syr. tobitani	3ss
Aque anisi q. s. ad.	3ii
	8

M. Sig.: To be taken at one dose; the dose to be repeated every four hours.

In gastric irritability:	
R. Acidi hydrocyanici dil.	m. iii
Liquoris bismuthi	3ss
Sodii bicarb.	gr. xx
Liq. morphine acetatis (1 p. c.)	
Spts. chloroformi, aa.	m. viii
Aque menth. pip. q. s. ad.	3i
	30

M. Sig.: One single dose every four hours.

To allay vomiting, the following combination is useful:	
R. Acidi hydrocyanici dil.	m. iv
Potassii bicarb.	gr. xx
Spts. ammon. arom.	m. xv
Liquoris bismuthi	3ss
Aque chloroformi q. s. ad.	3i
	30

In pruritus, the following is of value:

R. Acidi hydrocyanici dil.	3i
Liquoris plumbi dil. q. s. ad.	3viii
	240

M. Ft. lotio. Sig.: Apply locally to allay the itching on the unbroken skin. Or:

R. Acidi hydrocyanici	3ss
Liq. plumbi fort.	3i
Acidi carbonici liq.	m. v
Aque q. s. ad.	3ii
	60

M. Ft. lotio. Sig.: To be painted thinly over the irritable parts where the skin is unbroken.

[The foregoing should not be applied on mucous membranes nor on broken skin.]

In laryngismus stridulus:

R. Acidi hydrocyanici dil.	m. i
Spts. ammon. arom.	m. viii
Tinct. hyoscyami	m. iv
Syr. aurantii	m. xv
Aque anisi q. s. ad.	3ii
	8

M. Sig.: One such dose every four hours.

In spasmodic asthma:

R. Acidi hydrocyanici dil.	m. iv
Cresoti	m. i
Mucil. acacie	3ss
Aque cinnamomi q. s. ad.	3iv
	15

M. Sig.: One tablespoonful at once and repeat the dose at the end of an hour if not relieved.

In gastralgia with vomiting:

R. Acidi hydrocyanici dil.	m. iii
Cresoti	m. i
Liq. morph. hydrochlor. (1 p. c. B. P.)	m. xx
Sodii bicarb.	
Mucil. acacie, aa.	3ss
Aque dest. q. s. ad.	3i
	30

M. Sig.: Two tablespoonfuls at a dose and repeated in four hours if necessary.

Urem with Coma.

The following outline of treatment is recommended by H. J. Smith in *Med. Bull.* in the treatment of uremic coma: When the heart's action is feeble and accompanied by high arterial tension, nitroglycerin may be given hypodermically in doses of grain 1/100 (.0006), alternating with strychnia given in doses of grain 1/40 (.0015) each. The patient is placed in a hot pack and cold applied to the head. In conjunction with the hot pack, pilocarpin hydrochlorate may be given hypodermically in doses of grain 1/12 (.005) each to promote free diaphoresis and thus to aid in eliminating large amounts of urea.

Magnesium sulphate, 2 ounces (60.), given by rectum in a pint of warm water and the injection repeated several times, is recommended in order to withdraw large amounts of the serum from the system and thus to reduce arterial tension and to restore consciousness.

The duration of the hot pack must depend on the individual case, lasting from a few minutes to thirty-five or forty minutes, at the end of which time the heart should be observed and stimulants administered if necessary. Elaterin is of service at this stage of the treatment to promote free elimination by the bowels. It is given in doses of grain 1/4 (.008) each, together with large quantities of water if the patient regains consciousness.

As a diuretic the following combination is recommended:

R. Potassii acetatis	3iv
Infusi digitalis	
Infusi buchu, aa.	3vi
	180

M. Sig.: One tablespoonful every three hours. Or:

R. Hydrargyri chloridi mitis	
Pulveris seille	
Pulveris digitalis, aa.	gr. xx
	130

M. Ft. pillule No. xx. Sig.: One every four hours, and continue for one week.

AFTER-TREATMENT.

The after-treatment consists in giving a saline purge once or twice a week to assist in reducing the edema. For the high arterial tension spiritus glonoini is recommended, given in doses of 1 minim each (.06), three times a day. This may also relieve dyspnea if this is present.

To correct the anemia and to serve as a mild diuretic, Smith recommends liquor ferri et ammonii acetatis in doses to suit the individual case, and continued for several weeks. The diet during the active stage of the trouble should consist principally of milk and broths. After the acute symptoms have subsided lean meats may be allowed such as beef, mutton, lamb, broiled, roasted or stewed; well-cooked fish, green vegetables and stewed fruits.

Chronic X-Ray Burns.

In THE JOURNAL, March 10, 1906, we stated that Mr. Fuchs, a former x-ray operator, had used silver nitrate in full strength in chronic x-ray burns, with good results. This was an error; we should have stated that he had used C. P. nitric acid full strength.

Medicolegal

Actuality of Mental Suffering Attendant on Physical.

The Supreme Court of Florida, Division A, says, in *Western Union Telegraph Company vs. Wells*, that the intimate association between mind and body is a matter for discussion among psycho-physiologists; but to the laymen it is clear that a tribunal that allows damages for physical suffering can not deny damages for the mental suffering attendant on the physical. The one is as much an actuality as the other, and just as readily determinable by a jury.

Demonstration Before Jury of Nature of Injuries.

The Court of Civil Appeals of Texas says that during the trial of *Missouri, Kansas & Texas Railway Company of Texas vs. Lynch*, a personal injury case brought by the latter party, while a physician, the plaintiff's witness, was on the witness stand, the plaintiff's counsel had the plaintiff go around in front of the jury, take off his shoes and socks, and pull up his trousers and underwear, so as to expose his limbs above the knees, and then requested the physician to show the jury and demonstrate the plaintiff's sensibility or lack of sensibility his limbs. The witness then proceeded as follows: "As I said a while ago, he has a loss of sensation. His feet stay cold all the time. There is no feeling down here. You can pinch it as deep as you want to, and it don't make any difference. There is no sensation whatever. [Here the witness stuck pins into the plaintiff's limbs in various places, and continued the process until the blood was running freely from one place in one limb.] You can light a match there and burn him, if you want. The other is the same as this one [continuing to prick the other limb]. However, the left is a little better leg than the other. He seems to sort of bring it up from the hip and brace himself on it, so he can walk on his crutches. If it wasn't, he could not walk on his crutches." Then (turning to the jury): "If you would like for me to, I will stick a match under it. He won't have any pain about it at all. It will make a blister, of course." And, while said witness was on the stand, the plaintiff's counsel had the plaintiff to stand up in front of the jury, and requested the witness to remove his crutches. The witness then proceeded to take one crutch from under the plaintiff, leaving the plaintiff standing on the other, and then forcibly removed the latter, allowing the plaintiff to fall nearly to the floor, whereupon the witness, who was a very strong man, caught the plaintiff, raised him up, stood him erect, and then turned him loose and let him fall again, this time, as before, catching him just before he struck the floor. To these proceedings the defendant company objected, on the ground that they were improper and calculated to prejudice the minds of the jury. The objection was overruled and the evidence admitted. The court holds that the evidence was admissible as tending to show the nature and extent of the plaintiff's injuries. It says that this evidence could only have affected the amount of the recovery, and, as there was no complaint made that the verdict (for \$12,500) was excessive, the defendant could not have been harmed by its admission. The court also holds that there was no error in admitting the testimony of another physician that in his opinion, from all the history given him of the case and from what he saw about the plaintiff, and the length of time that had elapsed since the injury, it would indicate more the idea of permanency in his condition than not. It says that the witness was a medical expert, and could give his opinion, based on his examination and the history of the case received from the plaintiff. The defendant could, on cross-examination of the witness, have shown that the history of the case received by the witness from the plaintiff was not correct.

Application of Illinois Medical Practice Act.

The Supreme Court of Illinois in the case of *People vs. Langdon*, wherein it denied a rehearing in February, reverses the decision of the Appellate and Circuit courts. This was an action to recover the penalty for practicing medicine without a license from the State Board of Health, imposed by section 9 of the act in force July 1, 1899, entitled, "An act to regulate the practice of medicine in the state of Illinois, and to repeal an act therein named." The dates of the violations of the act charged were in 1903, without any averment that the defendant began the practice of medicine after July 1, 1899, and it was contended that without that averment no cause of action was stated. Thus the question raised was whether a person who has no license to practice medicine, who began such practice before July 1, 1899, when the present act took effect, and continued such practice thereafter without a license, is subject to the penalties named in section 9.

The Supreme Court says that it is clear that such a person comes within the express language of that section. He is a person who is practicing medicine without a certificate issued by the State Board of Health in compliance with the provisions of the act, and who does not hold an unrevoked certificate from the State Board of Health issued prior to the taking effect of the act. Having no license at all to practice medicine, he is within the terms of the statute and subject to its penalties.

But counsel contended that because section 2 only provided for the granting of licenses to persons entering on the practice of medicine after July 1, 1899, when the act took effect, the only persons subject to the penalties imposed by section 9 were those who began the practice after that date. The Supreme Court, however, does not see how that position can be maintained. It says that the provision of section 2 relied on is as follows: "No person shall hereafter begin the practice of medicine or any of the branches thereof, or midwifery, in this state without first applying for and obtaining a license from the State Board of Health to do so." Taking that section and the other provisions of the act together, they amount to this: Any person desiring to enter on the practice of medicine after the act took effect could only do so after first applying for and obtaining a license from the State Board of Health in compliance with the provisions of the act, and any person practicing medicine without a certificate issued under said act, or an unrevoked certificate issued under previous acts, was subject to certain penalties specified in section 9. The act is penal in character, and is to be strictly construed, but not with such technicality as to defeat its purpose. When the true meaning and intent of the act are apparent, the act is to be given effect in accordance therewith. The proviso excluding persons practicing medicine who hold unrevoked licenses issued by the State Board of Health prior to the taking effect of the present act can not be ignored in interpreting the act, and the proviso would be useless and senseless, if the legislature intended the act to apply only to persons who began the practice of medicine after the act took effect. To say that the legislature intended to grant immunity from prosecution to persons who were unlawfully practicing medicine at the time the act took effect would be wholly unwarranted. On the contrary, an unrevoked license or certificate issued under some previous act was required by the proviso.

In the case of *State Board of Health vs. Ross*, 191 Ill. 87, the question whether the State Board of Health could revoke certificates issued under a previous act was considered, and it was held that it could not. That decision was in accordance with the language of the act which provided for issuing licenses, and in one sentence provided that the board might refuse to issue a license for certain reasons, and might revoke such license for like causes. The provisions for granting, refusing to grant, or revoking a license under the present act relate only to persons entering on the practice of medicine after the act took effect. But that is an entirely different proposition from the one involved in this case. It does not follow from that decision that one who has no license under the present act or any former act may practice medicine without being subject to the penalties prescribed by section 9.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

March 10.

- 1 *Experimental Method in Sanitary Science and Sanitary Administration. W. T. Sedgwick, Boston.
- 2 *Review of Recent Observations on *Treponema Pallidum* of Syphilis. C. A. Pfender, Washington, D. C.
- 3 *Litholapaxy vs. Lithotomy. G. K. Swinburne, New York.
- 4 The Outlook for the Chronic Dyspeptic. M. I. Knapp, New York.
- 5 *Appendicitis, When to Operate. S. E. Sanderson, Detroit, Mich.
- 6 *Life Insurance Companies and the Prevention of Tuberculosis. C. L. Greene, St. Paul, Minn.

1. Sanitary Science and Administration.—Sedgwick states that comparatively few physicians or sanitarians are in a position to conduct artificial experiments, but that almost any wide-awake observer, whether he be a physician, physiologist, sanitarian or engineer, may, if he will, find going on all about him natural experiments, the conditions of which may often be learned with great accuracy, even after the experiment is completed, and which may yield conclusions quite as capable of verification as are those of experiments made in the laboratory. He pleads for better material on boards of health, claiming that it is time we should cease experimenting with political appointees and begin experimenting with something better than spoilsmen. Too often a hack politician or two, a second-rate physician or two, and one or more vain or place-seeking nobodies—useless but not harmless—make up local boards of health; and as no stream can rise higher than its source the services of such boards are disgracefully small in quantity and poor in quality.

2. *Treponema Pallidum* of Syphilis.—Pfender states that under the international code the present correct name of the organism now almost universally conceded to be the etiologic factor in the production of syphilis is *Treponema pallidum*.

3. Litholapaxy vs. Lithotomy.—Swinburne pleads for the more frequent use of litholapaxy, an operation too valuable to be lost. The technic is described and several cases are reported illustrative of the uses and limitations of the operation.

5. Appendicitis; When to Operate.—Sanderson believes that the safest general rule is to operate only when general peritonitis is not present. In regard to late operations, he says that no one questions the advisability of evacuating pus. As to the interval of operation, he says that if the attack has been unquestionably an inflammation of the appendix, especially if after-symptoms remain, operation is indicated; but if the symptoms are mild, and clear up entirely after the attack, it is best to await symptoms of an oncoming second attack before operation, in the meantime keeping the patient under observation.

6. Life Insurance and Tuberculosis.—Inasmuch as life insurance companies have a vital interest in the prevention of tuberculosis, Greene believes it desirable that the National Association for the Study and Prevention of Tuberculosis should endeavor to bring into active membership the medical directories of life insurance companies and seek to secure the active aid and co-operation of the companies in attempts to secure the passage and enforcement of laws directed to control tuberculosis, whether these relate to the building and maintenance of state or national sanatoriums, or to other vital matters. Arrangements ought to be perfected for the issuance of uniform sets of circulars, giving in plain and simple language such information as will serve to educate the masses, such literature to be printed and circulated by the companies through their agents and their ordinary mail service.

- 11 *Human Blood Pressure and Pulse as Affected by Altitude. C. E. Gardiner and H. W. Hoagland, Colorado Springs, Colo.
- 12 Inebriety Often a Form of Moral Insanity. T. D. Crothers, Hartford, Conn.
- 13 Vaginal Section in Relation to Puerperal Sepsis. J. S. Price, Beaumont, Texas.
- 14 *Korsakoff's Disease. E. L. Hunt, New York.
- 15 Open Safety Pin Swallowed by an Infant Six Weeks Old, and Successfully Passed by Bowel Six Days Later. B. Van D. Hedges, Plainfield, N. J.

8. Mastoiditis in Infants.—Oppenheimer gives the history of a patient illustrating the condition in which there is absence of prominent symptoms when the antrum is filled with pus, and declares that undoubtedly many deaths in infants ascribed to other causes result from a purulent inflammation of the mastoid antrum which has been unrecognized. In many cases the only evidence of the ear affection has to be gained from a careful study of the child for several days.

10. Serum Treatment of Hay Fever.—Knight sums up the present status of this treatment practically as follows: A final decision as to its value does not, as yet, seem warranted. There are so many discrepancies and sources of error that the problem is not easy to solve. The method of treatment varies greatly with the physician. There is also lack of uniformity in the preparation and use of the serum as well as in the general management of the patient. He thinks that it is fair to require an observance of the ordinary laws of health, even if such special precautions as excluding the night air during sleep, and so on, are not adopted. The strength of the serum and the sources from which it is obtained, as well as care and moderation in its administration, are important points. The writer believes from the mass of experience and literature relating to this subject, that a just estimate of the value of serum will soon be reached. The serum treatment at least does no harm even if it gives no better results than those attained by other methods.

11. Blood Pressure, Pulse and Altitude.—Gardiner and Hoagland found a rough ratio between pulse rate and blood pressure; the more rapid the pulse the lower the blood pressure. They also noted that when a pulse rate was but little affected by an altitude of 14,000 feet, the blood pressure was also more constant, and that cases of mountain sickness are accompanied by a fall in blood pressure and a rapid pulse rate. They conclude that patients suffering with high tension are likely to be benefited by being sent to high altitudes, while the change probably would be an undesirable one for patients in whom the blood pressure is abnormally low at sea level.

14. Korsakoff's Disease.—Hunt reports four cases. The first was alcoholic plus drugs; the second and third were both uncomplicated alcoholic; the fourth was post-typhoidal, and may have been complicated with alcohol. Only the first showed distinct neuritic symptoms, although both the second and fourth patients were weak on their legs, and probably in both the knee-jerk was diminished. All except the typhoid patient showed a tremor. All four displayed characteristic and identical mental symptoms—loss of memory for recent events, disorientation as regards time and place, confusion followed by violence and motor restlessness. Two of the four patients recovered; none died; two returned to their excesses, and their cases may practically be considered as chronic.

- 19 Congenital Occlusion of the Small Intestine; Operation; Autopsy. L. Davis and O. Richardson, Boston.

17. Virchow's Smooth Atrophy of Tongue in Syphilis.—As the result of investigations on a large number of patients Potter concludes that a normal base of the tongue is probably of considerable value in excluding an old syphilitic infection; whereas, a typical atrophy of the base of the tongue in an individual below fifty points to syphilis. A moderate or slightly marked atrophy of the base of this organ is of little value.

- 27 Peculiar Case of Infantile Palsy of Spinal Origin. F. Robbins, New York.
- 28 "Balsam of Peru in Castor Oil as a Surgical Dressing. E. V. Hubbard, New York.

26. Value of Throat Examination in Tuberculosis.—Harland points out the importance of the possible presence of tuberculosis when patients complain of catarrhal symptoms of the upper air tract.

27. Infantile Palsy of Spinal Origin.—In the case reported by Robbins, forceps, fillet, hand or pelvis did not form etiologic factors. A drooping of the right arm was noticed immediately after the birth of the infant. There was never the slightest evidence of voluntary control of the right arm. There was no evidence of cerebral implication. For experimental rather than for therapeutic purposes, the infant was stretched out at full length on the bed, its arms placed above its head, the middle fingers touching. A pull at his feet brought both arms down at once, flexed in the attitude of defense on the chest, both being flexed at the elbow, and then extended to drop along the body. This experiment was repeated several times and invariably yielded the same result. Robbins thinks it remarkable that exactly that position in which the greatest amount of tension is brought to bear on the fifth and sixth cervical vertebrae should have resulted in a temporary restitution of conductivity in the musculo-cutaneous nerve. He suggests that possibly the cervical roots of this nerve have only been stretched at their point of emergence from the spine.

28. New Surgical Dressing.—Hubbard speaks of a dressing for wounds which was first employed by the late Dr. W. W. Van Arsdale of New York, consisting of a mixture of balsam of Peru (3ss), and castor oil (3i). The combination forms a permanent mixture, moderately antiseptic, always viscous, and always serving the purpose of a dressing that will not harden and that will take up the wound discharges as fast as they are formed. Hubbard cites a number of instances in which he made use of this mixture with good results.

- 35 Centesimal Luxation of the Head of the Radius. W. E. Blodgett, Detroit.
- 36 Spontaneous Fractures with Rickets. H. O. Fells, Cleveland.

30. Traction in Hip Disease.—Bradford claims that in the treatment of hip disease a force which will counteract muscular spasm and draw the head of the femur away from the acetabulum, favors correction, the prevention of deformity and more rapid healing of the diseased bone tissue. Traction is not needed during the whole period necessary for the treat-

ment, but only during the stage of active muscular spasm. During the ulcerative stage fixation of the joints and strong traction are both needed in the convalescent stage, and limited motion of the joint is not injurious; but protection from violence is essential until the bone tissues have regained their normal strength.

31. Treatment of Hallux Valgus.—Wilson's paper deals with the clinical and radiographic conditions found to exist in 77 patients suffering from some form of hallux valgus and a report of four cases showing the results obtained by operation.

33. Multiple Cancellous Exostoses.—Davis reports two cases. The first patient was a man, aged 53, who when 10 years of age noticed a hard lump on the fourth finger of the right hand at the joint between the proximal and middle phalanges. About the same time hard lumps appeared on both humeri above the insertion of the deltoid muscles beneath the insertion of the pectoralis major on the antero-internal aspect. The lumps were hard, immovable, painless and attained their maximum size in a few months. Both forearms then became affected. Two years later both knees became involved and the legs became crooked. Later various joints became impaired. The condition progressed, gradually involving all the bones. The second patient was a child 3 years of age. The affection was noticed when it was about 1 year old. It involved the bones of the hand, arm, leg, several of the ribs and the scapulae.

- 43 Gastroenterostomy and Cholecystenterostomy. S. Lloyd, New York.
- 44 Medical Language. A. Rose, New York.

42. Simple Method for Detection of Spirochaete Pallida.—Goldhorn describes a method for rendering the spirochete of syphilis so plain and characteristic as to make its differentiation from the ordinary saprophytic spirochetes quite simple. The stain is prepared as follows: One gram lithium carbonate is dissolved in 200 c.c. of water, and 2 grams of medicinal methylene blue are added. When completely dissolved the solution is heated on the water-bath until a rich polychrome has formed. The solution is filtered through cotton. One-half of this polychrome is carefully acidified with 5 per cent. acetic acid until blue litmus paper shows a faint reddish tinge. The second half of the polychrome is added and into this corrected dye a weak watery eosin solution of about 0.5 per cent. strength is poured until complete precipitation has taken place. This point is determined by filtering a sample from time to time till the filtrate is of a pale blue watery color and slightly fluorescent. The mixture is set aside for a day and is then filtered through a double layer of filter paper. The precipitate is dried slowly at about 40 C. When dried it is dissolved in wood alcohol, making a strong solution, which is permitted to stand for a day, when it is again filtrated. To use this dye a sufficient quantity is dropped on an unfixed preparation so as to cover it; after two or three seconds it is poured off and slowly introduced into clean water, the preparation side turned down. When washed the preparation is drained and dried in the air. The *Spirochaete pallida* is stained a purplish color, which may be changed into a light black or black-brown by treating the specimen with Gram's or Lugol's solution.

- 47 "Trematic Diplegia; Operation; Benefit. W. S. Dentsch, St. Louis.
- 48 Plempus of Luvain. J. M. Ball, St. Louis.
- 49 "Two Unusual Cases of Tubal Pregnancy. C. H. Dixon, St. Louis.

45. Transfusion.—It is Dorsett's practice, after prolonged intra-abdominal operations, whether much or little blood has been lost, to inject into the rectum from one to two pints of

normal saline solution. In puerperal eclampsia there is no better remedy, in his opinion, than the introduction of normal saline solution into the veins. In these cases he thinks it best always to open a vein for the purpose of lessening the quantity of toxic blood in the circulation and then to supply the quantity removed by normal saline solution, which dilutes the toxins and renders them less potent, and also stimulates glandular excretion. Dorsett cites five cases illustrating the good results following this procedure. His experience with adrenalin in conjunction with normal saline solution is limited to one case. He thinks it is valuable as an adjunct because by its action the vasomotors are held in check and the intravenous saline solution equalizes the circulation. He warns against injecting too large quantities into the veins for fear of rupture of the vessels or fatal edema of the lungs.

49. **Unusual Cases of Tubal Pregnancy.**—Dixon cites two cases. The first patient, a multipara, menstruated regularly from May, 1902, till September, 1904, which period she missed. On September 14 she noticed a slight flow of blood which commenced with a severe pain lasting a few hours, starting in the region of the rectum and extending toward the stomach, accompanied by nausea. Eight days later she had a similar attack, only more severe. Two days later the pain was general over the abdominal cavity. There was muscular rigidity over the right inguinal region, flatness on percussion and some soreness. Vaginal examination showed a large swelling, soft and painful, on the right side, extending posteriorly. September 26 the patient had another attack of pain, more severe than the preceding ones, but of same character and location. She had been removed to the hospital the day before operation, and a few hours later the cavity was full of blood, the bleeding being from the right tube. Recovery was uninterrupted.

She menstruated regularly until May 22, 1905, when she had an attack of pain, paroxysmal in character, in the left side. She had none of the usual symptoms of pregnancy. A flow had existed since April 13. Examination showed a large swelling in the left pelvic region, pointing downward, painful and soft, with the uterus slightly enlarged. Operation showed rupture of the left tube, which was removed. Recovery was uninterrupted. In the case of the second patient the right tube was the one involved. In 15 cases seen by Dixon the pregnancy was always on the right side, except in the one in which there was a secondary pregnancy on the left side. In most of these cases there was rigidity of the muscles over the side of the trouble, which Dixon thinks is a point worth noting, because the absence of the rigidity usually is given as a differential sign between tubal pregnancy and appendicitis.

Iowa Medical Journal, Des Moines.

February 15.

50. *Shall Wholesale Poisoning Be Sanctioned by the People of the United States to the Detriment of the Masses, and the Advantage of a Few Privileged Criminals? C. F. Wahrer, Ft. Madison.

51. To Spread Sound Ideas Is to Work for Humanity. J. R. Jelefsky, Cedar Rapids.

52. *Case of Poisoning by Oil of Tansy. H. A. Leipziger, Burlington.

50. **Shall Wholesale Poisoning Be Sanctioned?**—Speaking of pure foods and the "patent-medicine" evil, Wahrer states that wholesale poisoning is being done all the time for the purpose of enriching a few at the expense of the health of the masses, who are asked to consume these poisonous products under the pretense that they are wholesome food. While adulteration does not always work injury to health it does deceive. Adulterations are not always for the purpose of deception, but often for the purpose of cheaply preserving articles from decay, so that they may easily be kept for an indefinite time without loss to the maker or the manufacturer. These preservatives, while insuring the ends of the producer, are usually poisonous and detrimental to the health of the consumer. Wahrer discusses the work done by Dr. H. W. Wiley of the Department of Agriculture and details the results obtained. He also speaks of the nostrum evil and the work done by THE JOURNAL, and by the various lay journals and magazines to suppress this evil.

52. **Poisoning by Oil of Tansy.**—Leipziger reports the case of a woman who took one ounce of oil of tansy for the purpose

of producing an abortion. Although she suffered intensely from symptoms of poisoning, she did not abort, but went on to full term, giving birth to a healthy female child.

Medical Society. W. J. Rothwell, Denver.

54. *Treatment of Scarlet Fever. N. Weist, Denver.

55. *Id. C. F. Schollenberger, Denver.

56. Id. D. R. Lacy, Denver.

57. Id. A. E. Grant, Denver.

58. Bright's Disease as a Gastrointestinal Toxemia. P. J. Pethuisje, Denver.

54. **Treatment of Scarlet Fever.**—In addition the customary treatment employed, Weist uses the following combination, which has yielded good results in every case:

R. Tinct. digitalis (fresh).....	5ss	2
Liq. ammon. acetat (fresh).....	3iss	6
Spt. ether nit.....	3ii	8
Syr. tolu.....	5ss	15
Aque cari, q. s. ad.....	3ii	90

M. Sig.: A teaspoonful every three hours.

The dose is varied according to the age of the patient. By giving this mixture from the beginning of the disease, every case, he states, has run an even uncomplicated course.

55. **Id.**—Schollenberger thinks that hydrotherapy is more useful to combat the temperature than medicinal antipyretics. In mild cases in which the temperature ranges from 100 to 102.5 F., and in which there are no heart complications, the following formula has given excellent results:

R. Tinct. aconit.....	gtt. xxxii	2 1/2
Antipyrin.....	gr. xxxii	2 1/2
Liq. ammoniac acetatis.....	5ss	15
Syrup, q. s. ad.....	3ii	60

M. Sig.: Teaspoonful every four hours for child 6 years old.

63. *Backache in Women and Its Treatment. W. E. Parke, Philadelphia.

64. Brometone in the Control of Epilepsy. W. Kempster, Milwaukee.

59. **Treatment of Uterine Inertia.**—Grandin gives first place to prophylaxis, keeping the nerve centers at par. He advises giving women who possess the characteristics of repressed nerve tone strychnia and quinin during the latter months of pregnancy, in the dosage of gr. 1/60 of the former and gr. 1 of the latter, three times daily. After the birth of the child the uterus should be given a chance to regain tone before resorting to attempts to deliver the placenta. Other causal factors being absent, Grandin proceeds at once to thorough tamponade of the uterus. On the removal of the gauze, within thirty hours as a rule, the uterus contracts.

Simple inertia in the first stage of labor, with membranes unbroken and patient getting sufficient sleep and nourishment, Jewett does not treat at all, except, perhaps, to eliminate recognized causes. In the presence of indications for prompt delivery he has found the employment of alternate hot and cold compresses over the abdomen most useful. He also administers quinin, in from 5 to 10 grain doses, or strychnin, gr. 1/30, every four hours. In inertia in the second stage, the treatment is the same as in the first stage. After full dilatation he resorts to the use of forceps.

When the membranes are unruptured and the pains are irregular, inefficient and powerless, after emptying both bladder and rectum, Polak administers morphin gr. 1/4 and atropin, gr. 1/50, and makes a firm vaginal tamponade of gauze. When the pains have been strong and regular, and then gradually diminish in force and frequency, he gives strychnin gr. 1/30 every half-hour until 1/5 gr. has been taken. When the inertia follows the delivery of the placenta, friction, ergot, and uterine tamponade are resorted to.

In the ordinary case of inertia Manton pins his faith to strychnin, quinin, and strong black coffee.

60.—This article appeared in *Med. Rev. of Reviews*; abstracted in THE JOURNAL A. M. A., Mar. 17, 1906, page 828.

61. **Treatment of Pneumonia.**—Johns favors the use of chloral and infusion of digitalis in the treatment of pneumonia, employed according to the methods described by G. W. Balfour. The dose varies with the age of the patient. For an adult the first dose is 20 grains of chloral in half an ounce of infusion of digitalis. The subsequent doses are 10 grains of chloral in half an ounce of infusion of digitalis, every four hours, to be continued until the temperature falls to normal. Johns has used this treatment for more than ten years in all kinds of cases and has found it equally good in all. [Is not 10 grains of chloral every four hours rather a large dose?—Ed.]

- 69. *Hydrocephalus and Rachitis; Their Treatment of Radiant Energy. M. A. Cleaves, New York.

65. **Acute Yellow Atrophy in a Child.**—Wentworth reports a case of acute yellow atrophy occurring in a boy of 5 years. At 18 months the patient had tuberculous peritonitis, from which he recovered without operation in about six months. At the age of 3½ years he had lobar pneumonia of the left lower lobe. The first symptom of the final trouble was a slight jaundice. This was followed in a day or two by vomiting and a slight degree of malaise. The child was about the house and out of doors until within four days of his death. On the sixteenth day of his illness he became delirious. The urine was negative. A diagnosis of the condition was not made during life. When the abdomen was opened at autopsy firm adhesions were found everywhere. The liver was not diminished in size, and the cut surface presented areas of a bright greenish-yellow color on a dark red background. The most striking feature of the case was the extreme degree of destruction of liver with the absence of macroscopic signs of atrophy. The liver cells were destroyed in at least three-quarters of the liver. The urine had not been examined for leucin and tyrosin.

69. **Röntgen Ray in Hydrocephalus and Rachitis.**—Cleaves reports a case of hydrocephalus in which the patient was exposed to the x-ray for five minutes, six inches from the target, biparietal, and treated to an arc light bath, the entire body being exposed to the energy of 10 ampere arcs or a total of 4,000 candle power. During the seven weeks the treatment was continued the child improved in every way. The mental improvement was more marked than the physical. The hydrocephalus also became less apparent in size. The second case was one of hydrocephalus due to rickets. This patient also improved under radiant light treatment.

- 76. A Neglected Duty. J. B. Taylor, Bloomington.

70. **Syphilitic Opacities of the Cornea.**—Posey cites the case of a lad of 17 who was the subject of congenital syphilis. During an attack of interstitial keratitis there appeared a triangular opacity in the superficial layers of the cornea which had to be differentiated from certain forms of keratitis parenchymatosa. The opacity was entirely avascular and was composed apparently of a series of fine lines which ran in a generally vertical direction from the base to the apex of the triangle. The rest of the cornea presented the general diffuse

haze and remnants of interstitial vessels which is usual after interstitial keratitis. The second patient presenting this unusual condition of the cornea was a woman 32 years of age, a subject of either late secondary or early tertiary syphilis. In the left eye there was a triangular zone of opacity corresponding in character, position, and extent to that seen in the first case.

71. **Herpes Zoster Ophthalmicus.**—Stieren reports a minimum and a maximum case of this affection. He does not believe in the acute specific hypothesis of the disease, since it never occurred in "epidemic." In all the cases which have come under his observation he has been able to trace a history of exposure to cold or dampness after some form of unusual exertion, with consequent fatigue, in individuals of sedentary habits.

75. **Creeping Disease.**—Under this title Moorhead describes a peculiar skin affection. The patient, a boy 5 years old, was said to be suffering from a Brazilian worm in his foot. The worm disappeared during the winter, only to reappear with the approach of the warm season. The infection was believed to have come from a family which came from Brazil and some of the members of which had their feet infected with this parasite. The worm travels in the layers of epidermis, pursuing rather a zigzag course, giving the skin much the same appearance as the surface markings of moles in the soil. The parasite moves from one-half to one inch during the twenty-four hours, usually at night, leaving a raised line of epidermis about one-eighth of an inch in width. The only effective treatment of the condition is excision of the progressive end of the line with plenty of tissue included to make sure of getting the parasite. Moorhead has succeeded in destroying the parasite in five cases by freezing the progressive or terminal end of the line with ethyl chlorid, one application being sufficient in each case.

81. **Value of Antiseptics.**—Gray is somewhat skeptical regarding the value of any of the antiseptics in general use in the treatment of infected wounds. He is convinced that both carbolic acid and bichlorid of mercury have been the means of causing death in more cases than they have saved from them. He favors substituting normal salt solution for these more severe agents and basing the treatment on the plan of elimination by evacuation of the pus and provision for drainage instead of persisting in the daily application of strong antiseptic solutions that in his opinion do more harm than good.

85. Occurrence of Meningococci in the Nasal Cavities.—Goodwin and Sholly isolated meningococci from the nasal mucus of 50 per cent. of meningitis patients during the first two weeks of the disease, and from about 10 per cent. of the people most closely in contact with them. They were frequently present in enormous numbers. Two cultures isolated from normal students were like meningococci culturally and in their pathogenicity, but did not have the same specific agglutinins. The authors believe that the finding of meningococci in great numbers in the nasal mucus of a large proportion of the patients and of those caring for them, and the absence of meningococci from the nasal mucus of a large number of normal persons examined, would strongly indicate the necessity of isolating cases of epidemic cerebrospinal meningitis, at least during the early weeks of the disease.

98. Use of Copper Sulphate in Water Filtration.—Clark and Gage believe that the treatment of water with copper sulphate or by storing it in copper vessels has little practical value, for the following reasons: 1. The use of any method of sterilization which is not absolutely effective is dangerous in the hands of the general user, tending to induce a feeling of false security, and leading to the neglect of ordinary precautions which would otherwise be employed. 2. The removal of bacteria, *B. coli* and *B. typhosus*, by allowing water to stand in copper vessels for short periods, while occasionally effective, is not sure, and the time necessary to accomplish complete sterilization is so long that the method would be of no practical value to the ordinary user. Furthermore, metallic copper seems to have little more germicidal power than iron, tin, zinc or aluminum. 3. Although the removal of *B. coli* and *B. typhosus* is occasionally accomplished by dilute solutions of copper sulphate, these organisms may both live for many weeks in water containing copper sulphate in greater dilutions than 1 to 100,000; and in order to be safe dilutions of 1 to 1,000 must be used, in which case the water becomes repugnant to the user because of its strongly astringent taste. 4. In some instances very dilute solutions of copper sulphate of colloidal copper absorbed from contact with clean metallic copper, appear to have a decidedly invigorating effect on bacterial activity, causing rapid multiplications, when the reverse would have been true had the water been allowed to stand the same length of time without any treatment.

1. Complications of Scarlet Fever.—Hunter records his observations of the relation of oral sepsis in scarlet fever to the complications occurring during that disease. One result stands out very clearly, viz., that the severity of scarlet fever, that is to say of the septic complications of it, is greatly influenced by the degree of oral sepsis present. Thus, of cases without oral sepsis only 35 per cent. had complications of moderate or severe degree; whereas of cases with oral sepsis 66 per cent. showed such complications. The severity of the initial angina also is affected by the presence of this previous sepsis. Hunter states that the actual frequency of the occurrence of complications of some kind or another is but little affected by the absence or presence of oral sepsis, but that the number of complications met in cases of oral sepsis is much higher than in those without it; and the severity of the complications met with is much greater.

3. Plumbism from Diachylon.—Hall and Ransom show that the custom of taking diachylon as an abortifacient has assumed such serious proportions in England that steps must be taken to stop this evil. They offer the following suggestions as the best method of dealing with the matter: 1. To compel by act of parliament the publication of its ingredients on the cover of every patent remedy. 2. To prosecute and to punish the makers and vendors of diachylon pills. 3. To seek the support of the lay press, and to invite it to abstain from publishing advertisements of "female irregularity" remedies. 4. To circularize, or otherwise to inform, all medical practitioners in the country of the possibility of such a cause in obscure cases of plumbism, so that they may recognize it and warn their patients. 5. Compulsory notification of all cases of abortion. 6. To make lead poisoning in women a notifiable disease. 7. To control, or to prohibit, the sale of diachylon.

4. Removal of Gall Bladder.—As the result of his own experience and that of others, Mayo Robson is convinced that there is an undoubted relationship between cholelithiasis and cancer of the gall bladder and ducts. He says that inasmuch as gallstones produce characteristic symptoms and as a rule, therefore, are easily diagnosed, and since they can be removed in the early stages, before serious complications have supervened, with very little risk (less than 1 per cent.) in his experience, the preventive treatment for cancer of the gall bladder is removal of the source of irritation. He is so impressed with the importance of this view, that he recommends the early removal of gallstones because the symptoms are likely to recur and lead to other complications. In a considerable percentage of such cases malignant disease is likely to supervene if the irritation is not removed.

5. Intrahepatic Calculi.—The patient whose case is related by Vachell Stevens was admitted to the infirmary complaining of jaundice and of painful swelling in the stomach. The liver extended down to within a finger breadth of the umbilicus. The constitutional symptoms were those of jaundice. The

patient became rapidly worse, the jaundice deepened, the hepatic enlargement increased, the stools became colorless and he died in a comatose state on the fourteenth day after admission. The liver weighed 97 ounces and over the whole extent of its surface were small projections caused by underlying calculi. Over the upper surface of the right lobe there were numerous white points which on section proved to be tiny abscesses containing thick pus. Since an attack of typhoid forty-one years previously (when 11 years of age) the patient had never been robust, although no symptoms suggestive of gallstones appeared until he was 23 years of age, since which time till his death, twenty-nine years later, he had suffered from frequent attacks of colicky pain attributed to dyspepsia. The gall bladder did not contain any stones.

8. Gastric Surgery.—Paterson reviews the immediate and remote results of gastrojejunostomy, the surgical treatment of gastric ulcer, of gastroenteritis and of hour-glass stomach.

11. Recurrent Herpes Gestationis.—Bryan reports a case of this kind occurring in a multipara. There was no history of syphilis. The rash appeared on the arms and consisted of erythema, papules and vesicles. It was irritating and painful. A few patches, without vesication, appeared on the thighs and body. The patient was about five months pregnant. The rash gradually extended over the rest of the body, leaving only the palms and the soles free, though the face was only affected by one or two spots. When the pain and irritation were most severe the forearms became hot and swollen and the vesicles were continually bursting, the fluid from them giving a sensation of scalding to the arms, whilst fresh crops rapidly appeared. These symptoms produced a good deal of insomnia. Treatment was futile. After six weeks of the disease the death of the fetus was diagnosed. The patient was delivered of a dead fetus and the rash gradually disappeared. About ten months later she again became pregnant and the rash reappeared. The eruption was always at its worst when the patient should have had her catamenial period, remaining at its height for about a week and then gradually subsiding, but never disappearing entirely.

13. Double Vaginal Cysts.—Jones' patient was a married woman, aged 35 years. She had had no children. In curetting for endometritis Jones found a cystic tumor of the size of a large pigeon's egg in the vaginal vault. Three months later the patient returned complaining of vaginal distress and pain. Low down on the posterior wall of the vagina was another cyst distended with fluid and nearly of the size of the one removed previously.

20. Ectopic Gestation During Lactation.—Six months after the birth of a child, and while the mother was nursing the baby, Weigall removed intact a perfect specimen of a tubal pregnancy about three inches in diameter, in the last inch of the tube near the fimbriated extremity. The uterus and tubes appeared to be normal. There were none of the usual symp-

oms of extrauterine pregnancy. The diagnosis was based on the softening of the os uteri and the presence of a rapidly forming tumor.

24. Report of the French Yellow Fever Commission in Brazil.—In this second report Marchoux and Simond explain that the *Stegomyia fasciata* is the only mosquito known which does not die after depositing its first batch of eggs. The female *stegomyia* is able to survive and to lay several batches. This long survival allows the virus of yellow fever time to develop in its body so that it is capable of infecting man. If it died regularly after laying its first batch of eggs—like other mosquitoes—yellow fever would be unknown among human beings. It is possible also, they add, that the virus is adapted to the organism of this special mosquito to the exclusion of all others. Infection of the *stegomyia* by heredity is possible, and a recently extinct focus might be relighted by this means. This fact is important for prophylaxis, although as a rule, infection by inheritance does not seem to play a very prominent part in the spread of yellow fever. The *stegomyia* does not eat the blood from the hemorrhages common during the second phase of yellow fever, nor the fluid of the black vomit nor the dejecta. The mosquito, even in captivity, does not feed on this material unless compelled by starvation. The larvae of the *stegomyia* raised in water containing fresh carcasses of infected mosquitoes do not contract infection, and the adult mosquitoes developing from them have no infecting power. When the infected *Stegomyia fasciata* is kept at a temperature of about 20 C. (68 F.) it does not seem to possess infecting power. In all their experiences at Rio de Janeiro the members of the commission never succeeded in infecting the *stegomyia* from persons during the incubation stage of yellow fever. The virus of yellow fever can be artificially transmitted from mosquito to mosquito in the laboratory, but probably not under natural conditions. They never succeeded in making several successive passages. They had only a single positive result in numerous experiments in which they tried to induce infection by hereditarily infected mosquitoes. The successful infection realized in this one case also proved to be exceptionally mild, suggesting that possibly the virus may become attenuated by its hereditary transmission.

25. *Spirochaeta Pallida* in Inherited Syphilis.—Levaditi describes with colored plates the histologic findings in 4 syphilitic new born infants, and in an infant who had succumbed to pneumonia, and in a macerated fetus from syphilitic parents. The *Spirochaeta pallida* was found in large numbers in the liver, lungs, suprarenal capsules, and skin, most numerous in the order named; it was comparatively rare in the other organs. The finding of such large numbers of these spirochetes in the macerated fetus, and also in those infants who had died after breathing only once or twice, disproves the assumption that the spirochete might be an agent of secondary infection. In the cases of acute and rapidly fatal syphilitic infection in these infants the spirochetes were found more diffusely distributed throughout the organism, while in the one case of tardy inherited syphilis the parasites seem to have been mainly confined to the organ principally affected by the syphilitic process, namely, the liver. This localization of the spirochetes in the viscera of the offspring of syphilitic parents suggests the possibility of an inherited syphilis exclusively confined to the splanchnic organs. It might develop without any syphilitic manifestations on the skin or mucous system. This essentially visceral form of syphilis might precede the appearance of external syphilitic lesions, and is interesting from the questions in regard to prophylaxis which it raises. The paternal origin of the inherited syphilis seems certain in one of the cases described. The spirochetes do not seem to linger by preference in the blood, but fasten themselves in the vessel walls and multiply there, passing thence into the cells of the

parenchyma and the connective tissue. They seem to be able to penetrate into the relatively intact protoplasm of certain epithelial elements, such as the cells of the liver and kidneys, of the suprarenal capsules, and probably those of the sweat glands. The pathogenesis of syphilitic lesions is thus explained by the findings of the spirochetes as they are traced through the endoarteritis and periarteritis into the connective tissue (infiltration by mononuclears and sclerosis), and then into the cells of the parenchyma (degeneration of the parenchyma). The maceration of a syphilitic fetus is probably an autolytic, fermentative process in dead tissues. The intratracheal death may be due to intense spirochete infection. Evidence of active phagocytosis against the spirochetes were apparent in all the infants. (See editorial.)

27. Emigration and Public Health.—Chantemesse calls attention to the lax measures in vogue in regard to emigrants passing through France to embark for America. He contrasts them with the strict regulations of the United States authorities, especially those enforced before allowing the embarkation of prospective emigrants on vessels bound for our ports. He states that nearly all emigrants from Greece, Syria, etc., pass through France, a total of 70,000 in 1904, and they are under no sanitary supervision after they arrive in southern France and are transported to Havre, changing cars frequently en route. Those found by the steamship company's medical inspectors to have a serious disease that would bar their admission to the United States are sent back to their country, while those with readily curable diseases, or those delayed for the five-day quarantine are boarded out in the town. They report to the inspector every day, and when cured are allowed to embark. In the interim they are liable to spread infection through the hotels and lodging houses where they stop while under treatment, entirely free from any medical sanitary inspection on the part of the town authorities. When rejected as suspicious by the inspectors they wander around the streets of the city ready to spread contagion if the suspected disease actually exists. The French laws on the subject of emigrants date from 1861, and he urges the passage of new ones to place the emigrant service on the same footing as in other European countries and in the United States.

28. Statistics and Prophylaxis of Tuberculosis.—The prolonged discussion on this subject shows how misleading statistics are liable to cause mistaken conclusions. The discussion brought out the experience of many practitioners, some advocating and others opposing compulsory notification of cases of tuberculosis. Nearly all accept the importance of notification of cases of death from the disease for disinfection of the apartment. It seems that the mortality from tuberculosis is much higher in France than in Germany, and that it is constantly increasing.

29. Phrenoptosis.—Glénard is the apostle of splanchnoptosis and here describes a condition which he calls phrenoptosis, that is, downward displacement of the diaphragm. He considers it responsible for the conditions known as movable heart and cardioposis, defining movable heart as a cardioposis, while the cardioposis is the consequence of the phrenoptosis; the phrenoptosis in turn is merely an accessory episode of the general tendency to ptosis. He states that enteroptosis is a nutritional affection of hepatic nature. The same causes that induce liver affections preside over its origin. It is a malady built up from detached fragments of five morbid groups: dyspepsia, neuropathies, liver affections, nutritional disturbances, and a fifth group which includes movable kidney, movable liver, movable spleen, and movable uterus. It is the character of the ptosis which cements together these fragments. Enteroptosis is the cause of one-third of all the dyspepsias and neuropathies in women, and in every 100 cases fully 80 of the patients are women. Once recognized it is readily curable, but it is incurable when not

diagnosed and the special indications treated. The efficacy of appropriate treatment, he believes, is one of the arguments in favor of accepting the affection of a definite morbid entity. The most effectual measure in combating the condition is an appropriate sustaining corset, as he has described in detail in various communications. The latest appeared recently in the *Revue des Maladies de la Nutrition*, 1905.

35. Opening the Pleura Without Pneumothorax.—Tuffier recalls his research in 1895 in which, with Hallion, Quénu and Longuet, he demonstrated that it is possible to inflate the bronchi sufficiently to prevent retraction of the lung when the chest is opened, without interfering with the general circulation. An apparatus was devised and presented to the Société de Chirurgie with which the patient breathed only air under pressure. The apparatus is merely a tube introduced through the mouth into the trachea; an elastic bag around the tube is inflated to plug the air passages outside of the tube. Air under pressure can then be pumped through the tube into the lung and all retraction prevented. It proved very successful on dogs. At first his apparatus was regarded as too complicated in comparison with the benefits to be gained from it, pneumothorax not being regarded by others as such a drawback as he considered it. The subject gained new interest, however, when Sauerbruch invented his air chamber in which operations are performed under minus pressure, while the head of the patient projects outside the chamber and the anesthetic is given outside. Brauer's apparatus reverses the principle, the head of the patient being inside a small air chamber in which the air is kept at plus pressure. This principle is the same as that on which Tuffier's early apparatus was based. Tuffier has performed three important operations with the aid of the Brauer hyperpressure apparatus. (He has both the Sauerbruch and the Brauer apparatus installed in his service.) It worked to perfection, he says, but both this and the Sauerbruch chamber are so extremely complicated that his early apparatus based on the same principle as Brauer's, seems simplicity itself in comparison. He gives illustrations of it (as also of the Sauerbruch and Brauer apparatus), and describes its workings in his experimental experiences with it. The Sauerbruch chamber might be utilized, he remarks, in operating on the brain or elsewhere when venous hemorrhage is feared. Under strong minus pressure there would be less danger that the veins would bleed much. The Brauer apparatus can be used only for operations on the lungs. In all work of the kind, Tuffier suggests that mixing oxygen with the air inhaled would lighten the task of the lungs, and facilitate the operation.

41. Treatment of Lead Colic.—Delaferte and Dubois report the successful application of epidural injections of cocaine as a means of relieving lead colic. No disturbances were observed in any of the 16 cases in which this treatment was applied. The pain vanished almost at once after the lumbar injection of the anesthetic.

- 49 **Laceration of Cervix in Primiparae.**—Scheurer reviews 99 cases of laceration of the cervix in primiparae. Bleeding was the only symptom that called attention to the tear, and this was sometimes out of all proportion to the extent of the laceration. In more than one-fourth of all the cases the laceration involved more than half of the vaginal portion of the cervix. More than 50 per cent. of the extensive lacerations occurred in deliveries in which obstetric-operative measures had been applied. Abnormal position of the head and large size of the child favor injury of the cervix. It was impossible to detect any influence on the morbidity of the puerperium or on the involution of the uterus from the lacerations.

50. **Trichiniasis and Eosinophilia.**—Stäubli's experience with 7 cases of trichiniasis emphasizes anew the value of eosinophilia as a sign of the affection. The number of eosinophiles began to increase about nine days after ingestion of the infected meat. The eosinophilia, he shows, is connected with the migration of the embryos or their penetration into the muscles. The young brood are distributed by way of the vascular system; large numbers being evident at times in the blood of the heart. He saw no evidences of local production of eosinophiles at points where the muscle was specially invaded. The eosinophilia must be regarded, he states, as a reaction on the part of the organism to substances which pass into the blood from the embryos, or possibly from the degenerated muscle substance. His experiments on animals confirmed the assumption that a rapid destruction of lymphocytes is a bad sign. Four of his cases terminated fatally, and in these he noted the combination of Kernig's sign and absence of the knee jerks. In all his cases the diazo reaction was pronounced, a point which may aid in differentiation.

52. **Blood Pressure and Hypertrophy of Heart in Nephritis.**—Loeb insists that the high arterial pressure is primary and the hypertrophy of the heart a secondary phenomenon in acute and chronic nephritis. He accepts the elevation of the blood pressure as a regulating phenomenon—the work of the glomeruli. Whether this occurs by chemical or reflex means is still a question. The arterial pressure in his experience

always rose when uremia was impending or established. Patients leading tranquil lives, on a light diet, kept the blood pressure at a moderate height. Change to a mixed diet, especially when meat and salt were taken, always increased the pressure.

58. **Experimental Study of Gout.**—Van Loghem summarizes the results of his research in the statements that uric acid and sodium urate are soluble in the body fluids of the rabbit and dog, the former much more than the latter. Alkalies taken internally favor experimental deposition of the urates, while acids prevent it. This suggests, he adds, the possibility that hydrochloric acid might be used for a rational prophylaxis of the formation of urates in man.

59. **Atrophy of Muscles in Cerebral Paralysis.**—Steinert has been studying the muscular atrophy in 68 cases of paralysis. His results harmonize with the conclusions of previous similar research, and throw light on several new points. It seems to be an established fact that cerebral paralysis of the extremities is followed by atrophy of the muscles in the limbs as regularly as is the case in every peripheral paralysis. He found the atrophy more pronounced in the cases of flaccid than of spastic paralysis.

60. **Pathogenesis of Tetany.**—Pineles presents an array of arguments to prove that all forms of tetany in man and animals have a common origin in an insufficiency of the "epithelium bodies," the parathyroids. The thyroid gland may be entirely removed, without subsequent tetany, if they are left intact. These bodies perform the task of rendering innocuous certain toxic substances generated in the body. These toxins are the tetany toxins, and when the organism is not protected tetany is liable to develop. He is at work now on an extract of the parathyroids which he hopes will prove an effectual remedy for the prevention and cure of tetany.

61. **Latest Views of Typhoid and Paratyphoid.**—During the last two years Brion and Kayser have made extensive clinical and bacteriologic studies in over 200 cases of typhoid fever. The definition of infection with the Eberth-Gaffky bacillus, based on their findings, is merely the vague description: "a febrile condition not to be explained by any evident findings in any organ, and in which there is no exanthem nor special course characteristic of any other disease." This definition is important theoretically, as it shows that it is impossible to determine any clinical symptomatic entity from the identity of the causal agent of the infection. They ascribe infection to the tonsils: "The portal of entry lies either in the gastrointestinal tract or above the stomach, perhaps in the region of the tonsils. The frequent positive bacteriologic findings in the tonsils suggest the plausibility of the latter assumption, and explain the first symptoms of typhoid—which are always of a general nature—as due to the entrance of the bacilli from the tonsils into the lymphatic system and thence into the blood. The bacilli were found in the blood at the very beginning of the disease in 94 per cent. of the cases, and they gradually disappeared from the blood as the disease progressed. The bacilli circulating in the blood and lymph induce the characteristic foci in spleen and liver, in the mammary and other glands, and in the intestine, in the brain, lungs and serous membranes, and in the skin (roseole). Any organ may be affected, the lymphatic apparatus with especial frequency. The lesion in Peyer's patches is a phenomenon co-ordinated to the entire process, only it occurs with exceptional frequency. It is entirely absent in some cases, and this seems to be the rule in children. After the bacilli have disappeared from the blood and other organs they may lurk for months and years in the gall bladder, particularly when there is residual bile from the presence of gallstones. The typhoid affection may persist in the gall bladder as a purely local process for a long time. The irritation of the body cells from the presence of the bacteria results in the production of substances which pass into the body juices and are the cause of agglutination and of the specific bactericidal action." Their experiments with animals and with human subjects effectually demonstrated that the intestinal tract is not a favorable soil for the setting of the typhoid bacillus. Its growth is checked or it is entirely destroyed in the intestines. They regard it as difficult to imag-

ine any circumstances which would render it possible for the bacilli to make their way primarily into the blood through the intestinal walls. One of their findings to which they call attention is the spasmodic way in which the bacilli were found in the dejecta; at intervals none was to be found in the diarrhetic stools, even at the height of the disease. In a number of dubious cases—which later proved to be typhoid—no typhoid bacilli could be discovered in the stools at first. This is another argument in favor of the assumption that typhoid does not always commence in the intestines, but may start as a lymph and blood affection (possibly entering by way of the tonsils). The positive findings in the stools always increased from about 32 per cent. in the first week to about 45 per cent. in the third week. As the final conclusion from this extensive research, Brion and Kayser assert that the assumption of the symptom-complex of typhoid fever as an etiologic entity must be abandoned. It must be regarded as a group of affections not to be differentiated clinically, whose causal agents form a special group apart.

68. Transmission of Syphilis to Monkeys.—The results of Neisser's extensive researches were mentioned in the news columns on page 287. He had nearly 900 monkeys at his disposal, and found that the lower types, as well as the higher, were susceptible to syphilitic infection, although in a lesser degree. The general symptoms observed in the higher animals seldom appeared in the lower types. The animals were inoculated by rubbing the material into deep scarifications. Subcutaneous injection of material or vaccine always gave a negative result. The sound organism seems to be able to destroy the virus inoculated into the subcutaneous tissue, although it may prove to be possible to produce an antitoxin in this way. Passage of the virus through several animals seemed rather to enhance than to attenuate its virulence. The *Spirochaeta pallida* was found in a number of cases, confirming Schaudinn's statements. Neisser's assistants, Baermann and Halberstädter, have been left behind in Batavia and are continuing the research. To date it has not resulted in any definite general conclusions.

75. Inexpensive Lantern Slides.—Schumburg outlines the drawings on a sheet of glass, fixed with shellac and coated with soot.

76. Operations on Pancreas and Stomach.—Körte has operated on 6 patients on account of acute pancreaticitis and fatty necrosis, with a favorable outcome in every instance. Early intervention and drainage are able, he thinks, to prevent the spread of the pancreatitis and suppuration. He describes the details of his 2 last operations of this kind, and also of 7 operations on the stomach. He operates without delay even in the acute stage of pancreatitis, hoping thus to avert suppuration and necrosis. The attack resembles gallstone colic except that there is more collapse, and symptoms of peritonitis develop in the upper abdomen. In one of his stomach cases

there was great dilatation of the stomach without stenosis of the pylorus. The extreme gastropexy kinked the pylorus, and also entailed complete motor insufficiency. All his patients recovered except one who had cancer of the stomach on a basis of gastric ulcer. The patient, a woman, deferred the operation until she became too weak to rally.

77. Spirochetes in Yaws.—Castellani states that he found spirochetes of the pallida type in 11 out of 14 cases of typical yaws on the island of Ceylon.

78. Experimental Anemia.—Rothmann has been studying the spinal cord of dogs after severe anemia had been induced by means of pyroin. A systematic degeneration was evident, even when no functional demands were made on the cord.

79. Differentiation of Asthma.—Eisner has encountered a number of cases in which the symptoms indicated hay fever or asthma, but the absence of reaction to pollen disclosed that the asthma was a purely nervous affection. He makes the pollen test with pollen of grains, grasses and corn; he grinds it in salt solution and centrifugates it. If the albuminous solution thus obtained is introduced into the eye of a susceptible individual, the eye itches, becomes bloodshot, and in the severer cases the usual train of hay fever symptoms follows unless aborted by appropriate measures. Among 100 asthmatic persons thus tested in Berlin, only 4 were found who failed to show the specific reaction to the pollen. This shows that the tendency to hay fever is more prevalent in Germany than hitherto supposed, as the pollen test causes no disturbance whatever in normal persons. In conclusion, Eisner discusses the reasons for absence of antitoxin formation after injection of albumin.

81. Quantitative Test for Acetone.—Bluth's test is based on the delay in the change of tint when the urine is treated with sodium nitroprussid, sodium hydrate and acetic acid. The more acetone present, the longer the interval before the change of tint. His test, he says, dispenses with repeated distillation and subsequent titration; it requires only from fifteen to thirty minutes, and in regard to accuracy leaves nothing to be desired.

82. Dislocation of Head of Femur Through Obturator Foramen.—Riedel observes that many experienced surgeons have never encountered this condition, but he has had 3 such cases. He was able to reduce the dislocation by a simple maneuver which he describes.

83. Mobilization of Duodenum as Aid in Deep Gallstone Operations.—Lorenz describes the particulars of 5 cases of gallstones, requiring intervention in the deep biliary passages, in which he mobilized the duodenum as a preliminary measure. The advantages of this procedure were very great, and it was easily accomplished, although the conditions were exceptionally grave.

86. Polycystic Degeneration of the Kidney.—Sieber's long article discusses the origin of the condition and describes a case personally observed in a woman of 46. He then summarizes 211 cases he has found in the literature, all in persons

over 20 years of age. He further refers to 32 published reports of cases in children from 8 weeks to 19 years old. In 9 cases the affection was found to be unilateral and in 150 bilateral. In the others the condition of the second kidney was not mentioned. In about one out of every 8 cases the affection caused no symptoms during life and was an autopsy surprise. In 62 cases nephrectomy was undertaken, generally on a mistaken diagnosis, and death followed in 20 out of the 61 cases in which the result is known. In 9 of the remaining 41 cases symptoms developed later indicating disease in the other kidney. Sieber concludes from his summary that operative intervention in case of polycystic degeneration of the kidney should not be advised unless under compelling circumstances, such as suppuration and anuria. Under other conditions, expectant, palliative treatment should be the rule. All injurious influences that might increase the demands on the kidneys should be warded off, and the heart action should be carefully supervised. The treatment, on the whole, should be similar to that for contracted kidney. On account of the frequent hereditary character of the affection the patient's near relatives should also be examined and warned to avoid all injurious influences liable to favor the development of a kidney affection. The symptoms of polycystic degeneration are uncertain and the course of the affection is irregular, so that the diagnosis is difficult. Only 21 of the cases on record were correctly diagnosed during life. The first and most important symptom is generally the increase in size of the kidneys. These organs may become so much enlarged that they nearly touch on the median line, although one is usually much larger than the other. In only 26 cases was it possible to palpate a tumor on both sides. Pain may or may not be present, and the urine is not characteristic. It is generally acid, limp and bright yellow, with little sediment. Hematuria was noticed in about a fifth of the cases. The general symptoms are all more or less the consequences of a chronic or acute uremia. The digestive apparatus is especially affected, and its disturbances may overshadow all the other symptoms, sometimes for years.

87. Gummatous Osteomyelitis of Long Bones.—Landow claim it difficult to differentiate a case of osteomyelitis in the long bones of a girl of 16. The symptoms and location of the lesions suggested a tuberculous process. Hyperostosis of the tibia and the fact that none of the bone foci had ever displayed a tendency to suppurate, cast some doubt on this diagnosis. The idea of syphilis was discarded, as no trace of it could be found in the history and there were no other signs of syphilis, while Landow was assured that prolonged treatment on the assumption of inherited syphilis had been applied previously without any result. Operations disclosed extensive osteomyelitis and necrosis of the bones, but no tubercles nor staphylococci. Proper antisypilitic treatment cured the recent foci, but operative intervention was required for the old lesions. The patient was restored to comparative health.

90. Necessity for After-Treatment of Surgical Tuberculosis.—Kraemer cites a number of instances from his own experience in which patients apparently healthy for a few years after operative treatment of some local tuberculous lesion, later developed pulmonary phthisis. The persistence of a latent focus after what was supposed to be radical extirpation of the tuberculous process would have been revealed in these cases if tuberculin had been injected after the operative wound had healed. He consequently advocates testing with tuberculin as a routine measure after he healing of any surgical or gynecologic tuberculous process treated by conservative or operative measures. The tuberculin test will show either that the patient is free from tuberculosis, in which case he can be dismissed from further treatment, or that some latent focus still persists, in which case the local reaction will frequently point to the site of the lesion. Persons in this latter category should be given appropriate treatment until their entire freedom from tuberculosis can be definitely established. By these means it will be possible to save these individuals from a revival of their tuberculous affection by propagation of metastasis, and also to protect other persons from contamination by their infectious secretions, and unborn children from inherited infection. It should be accepted as a prin-

ciple that every individual with a latent tuberculous focus is to be regarded as already a candidate for consumption, and treated accordingly.

100. Viscosity of the Blood.—The research reported by Bence was conducted at von Koranyi's clinic at Budapest. It shows that the viscosity of the blood increases and subsides with the proportion of carbon dioxide in the blood. The latter acts on the red corpuscles, modifying their size and surface, and thus rendering the blood more or less fluid. The relations between the proportion of carbon dioxide and the viscosity can be observed in the circulating blood. The increasing viscosity of the blood from excess of carbon dioxide overburdens the heart. If the overcharge of carbon dioxide is the consequence of cardiac insufficiency, it tends in turn to increase the latter. Inhalation oxygen in appropriate cases reduces the viscosity of the blood unduly laden with carbon dioxide, as it promotes the elimination of the latter. By this means it is possible to relieve to a certain extent the overburdened heart. The blood in nephritis is less viscous than normal blood, probably from the excess of water. Attempts to influence the viscosity of the blood by varying the food gave negative results in his experiments on animals.

101. Physiologic Significance of Radioactivity of Mineral Waters.—Bergell and Bickel have been continuing their research on this subject, their findings corroborating their previous assertions in regard to the powerful physiologic and biologic influence of the natural radioactive emanations of the mineral waters. All observations to date have shown that waters rising from the depths of the earth are endowed with marked radioactive powers while surface spring waters are comparatively free from it. The waters lose their radioactivity rapidly after they are taken from the earth. Tests with Wiesbaden thermal waters showed that the digesting power of gastric juice in a test-tube was increased by the radioactivity. If thermal water was added to pure gastric juice, the digesting power of the juice was reduced by the dilution, but the reduction was less marked when the waters were still radioactive than when they had lost their radioactivity. Kahmann has recently announced that Gastein waters arrest the development of the *Bacillus prodigiosus* as long as they still possess their radioactivity, but not after they have lost it. The conclusions of the research all point to the assumption that it is possible for physiologic and biologic processes to be influenced by the radium emanations in mineral waters.

103. Cytology of Cerebrospinal Fluid in Nervous Affections.—Samel tabulates his findings in a dozen cases of tabes, meningitis, paralysis or other nervous affections. They differ from those of other investigators in certain respects, as he re-

lates in detail, comparing them with the data in previous articles on the subject.

101. **Healed Dissecting Aneurism of the Aorta.**—Börger has found 18 cases of dissecting aneurism of the aorta terminating in recovery on record in the literature, and describes a case personally observed at Erlangen. The aneurism in this case was evidently the result of a so-called internal trauma. It healed as the dividing wall became perforated, allowing the layers of the wall to grow together once more. The conditions in the circulation, however, had been rendered so unfavorable that the already hypertrophied heart gave out in the course of a year.

106. **Influence of Water Content of Blood on Size of the Red Corpuscles.**—The research described was made on 200 patients with dropsy, severe diarrhea or other conditions causing great difference in the proportion of water in the blood. It demonstrates that hydremia has nothing to do with the production of megalocytes. Also that the biconcave microcytes are intact red corpuscles.

107. **The Blood in Children with Adenoid Vegetations.**—Scheier found the proportion of hemoglobin about 13.8 per cent, below normal in the children with adenoid vegetations whom he examined. The red corpuscles were about the usual number, but there were always from 14,000 to 17,000 white corpuscles, and sometimes 21,000 and 24,000. The small and large lymphocytes were unusually numerous, and the multinucleated somewhat diminished. A slight degree of chlorosis with leucocytosis, specially lymphatic, was the rule. Removal of the growths caused improvement; the hemoglobin rose to 74, 80 or 92 per cent, in the course of from one to several months afterward, while the leucocytosis declined. In conclusion he remarks that the adenoid vegetations in the nasopharynx are not the only manifestations of hyperplasia in the lymphatic system. The lymph glands in the neck and under the jaw are always more or less swollen in these cases. The swelling almost invariably subsides after removal of the adenoid vegetations, and the somewhat low blood pressure rises to approximate normal.

109. **Clinical Examinations of Feces.**—Oerum has been studying the intestinal functions in the clinic for more than a year, following the directions of Schmidt and Strassburger. The test diet consists of 0.5 liters of milk and 50 gm. zwieback early in the morning; for breakfast, 40 gm. oatmeal or 0.5 liters of oatmeal gruel, 10 gm. butter, 200 gm. milk, 300 gm. water and one egg (strained); for dinner, 125 gm. chopped beef (weighed raw), browned over but still raw inside, and 250 gm. mashed potatoes (made with 100 gm. potatoes, 100 gm. milk and 10 gm. butter). The afternoon meal is like the earliest meal, and the supper like the breakfast. A tablet of 0.3 gm. of pulverized carmin is given usually at the commencement and conclusion of the test diet, which is kept up for three days or longer. For the macroscopic examination he takes a lump of feces the size of a walnut and rubs it in a mortar with water and then spreads the soft mass in a thin layer on a wide glass saucer standing on a black background. He then examines it for mucus, evidences of parasites, pus, foreign bodies, etc., relics of connective tissue from the raw meat, muscle fiber and potato, and for crystals of ammonia or magnesium phosphate. Microscopic and chemical tests are then applied. His experience with the albin test for invisible blood has been extremely favorable in 100 cases. He regards it as a great advance in our means of detecting carcinoma of the intestinal tract and latent ulcer in stomach or intestine. He describes the technique for this and for various other tests, and the importance of the findings is emphasized. He determines the proportion of water by weighing a jar containing some dry sand and then pouring 10 c.c. of the diluted feces on

the sand, with a little diluted sulphuric acid. The jar is then dried out to a constant weight, the difference between the two weights being the weight of the dry substances in 10 c.c. of feces. When an abnormal proportion of fat is discovered in the diet, he limits the intake of fat, which sometimes materially benefits chronic intestinal affections. His experience has confirmed the assumption that chronic constipation in the majority of cases is due to exceptionally perfect utilization of the food ingested with the consequent lesser secretion in the intestines from lack of stimulation from fecal masses.

110. **Pathogenesis of Congenital Heart Affections.**—Sundberg describes the autopsy findings in a case of congenital deformity of the heart. The patient, a man, lived to the age of 22 although with various malformations of the heart. They all bore the appearance of having been the result of excessive bending over of the head during uterine existence.

Books Received

Acknowledgment of all books received will be made in this column and this will be decided by us as a favor to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or to the interests of our readers.

CLINICAL APPLIED ANATOMY, or the Anatomy of Medicine and Surgery. By Charles R. Box, M.D., B.Sc., M.R.C.P., F.R.C.S., physician to out-patients of St. Thomas's Hospital, and W. McAdam Eccles, M.S., F.R.C.S., Assistant Surgeon, Joint Lecturer on Anatomy and Demonstrator of Operative Surgery at St. Bartholomew's Hospital. Illustrated by 100 plates, of which 12 are colored, and 8 figures in the text. Cloth. Pp. 471. Price, \$4.00. Philadelphia: P. Blakiston's Son & Co., 1906.

THE WORLD'S ANATOMISTS. Concise Biographies of Anatomic Masters, from 300 B. C. to the Present Time, whose Names Have Adorned the Literature of the Medical Profession. By C. W. H. Kemper, M.D., Professor of the History of Medicine in the Medical College of Indiana, Indianapolis. Revised and enlarged from the original serial publication in the *Medical Book News*. 11 illustrations, 9 of which are portraits. Paper. Pp. 79. Price, 50c. Philadelphia: P. Blakiston's Son & Co., 1906.

SCIENTIFIC MEMOIRS BY OFFICERS OF THE MEDICAL AND SANITARY DEPARTMENTS OF THE GOVERNMENT OF INDIA. Issued under the Authority of the Government of India by the Sanitary Commissioner with the Government of India, Simla. (Calcutta: Office of the Superintendent of the Printing, No. 21, Strand.) 1. The Sanitary Organization of Anti-Typhoid Vaccine, by Captain George Lamb, M.D., I.M.S., and Captain W. B. C. Forsier, M.B., D.P.H., I.M.S., Price, 6s. and 6d.

THIRD TREATISE ON THE EFFECTS OF BORAX AND BORIC ACID ON THE HUMAN SYSTEM, with Diacrisis, being a Critical Review of the Report of Dr. H. V. Wiley, Chief of the Bureau of Chemistry of the U. S. Department of Agriculture, to the Secretary of Agriculture. By Dr. Oscar Liebreich (Translated from the German). Paper. Pp. 70. Price, \$1.75. Philadelphia: P. Blakiston's Son & Co., 1906.

THE NATURAL LAWS OF SEXUAL LIFE, Medical-Sociological Researches by Dr. ARON NYSTROM, Stockholm. ACUTE DILATATION OF THE STOMACH.

WITH REPORT OF TWO CASES, ONE OF WHICH COMPLICATED PNEUMONIA AND ENDED IN RECOVERY.

JAMES B. HERRICK, M.D.
CHICAGO.

Acute dilatation of the stomach is a rare condition. In 1903 Thomson¹ collected less than fifty cases. A few have been reported since. It is a grave condition, truly appalling, as its high mortality well indicates. Its recognition is not always easy, yet important, as it is probable that the earlier treatment is begun the better is the outlook. I report these two cases of acute dilatation of the stomach, therefore, because the rarity, gravity and importance of recognition of the disease make it desirable that every observed case should be put on record. One of these cases recovered—the first recorded recovery, I believe, where the disease has been a complication of pneumonia or pleurisy; in the other patient an autopsy was not to be obtained. I can, therefore, make no contribution to the morbid anatomy of the disease, knowledge concerning which is extremely scanty, but very desirable as helping one to a better insight into the as yet little understood pathogenesis and the true etiology.

I have thought it wise to add to the report of these cases a brief summary of the main points in the clinical history of this condition. One desiring fuller information can find it in the monograph of Campbell Thomson.¹

CASE 1.—E. S., male, aged 36, entered my service at the Presbyterian Hospital, Feb. 13, 1904.

History.—His family history was good, with the exception of a doubtful tuberculosis in an older brother. He had had measles as a child, smallpox in 1881 and a fever, probably typhoid, in 1886. He was a moderate user of tobacco. Up to one year ago he had used alcohol quite freely. He had been bothered with his stomach only after spells of excessive drinking. For the past year he had not been drinking and had been in excellent health. February 10 he was suddenly seized with a sharp pain in the right side of the chest. This was followed by chilliness, headache, cough, diarrhea, vomiting and fever.

Examination.—On examination he was found to be a well-nourished man of moderate stature, with physical signs of consolidation, evidently pneumonic, of the upper lobe of the right lung and the upper portion of the lower lobe of the same side. Dullness, bronchial breathing, increased vocal resonance and fremitus and a few fine crackling râles were plainly made out. The patient was somewhat cyanotic and breathed with evident pain. There was a labial herpes. The tongue was dry. He was clear mentally. The physical examination as to the special senses, nervous system, heart, liver, rectum, genitalia and extremities was negative. The skin showed pitting from

variola. In the record of the examination of the abdomen it is recorded that "the lower border of the stomach is apparently above the umbilicus." "The spleen can be distinctly felt on deep inspiration."

Blood.—The blood on admission showed 5,280,000 erythrocytes, 33,100 leucocytes, nearly all polymorphonuclear, and hemoglobin 98 per cent.

Urine.—The single specimen of urine obtained on admission, specific gravity 1022, showed a heavy trace of albumin and contained numerous granular and hyaline casts. A twenty-four hour specimen, 1,000 c.c., specific gravity 1021, likewise contained a considerable amount of albumin, with many granular and hyaline casts.

Sputum.—In the viscid, rusty sputum, diplococci, many with capsules, were very abundant in stained smear preparations.

Course of Disease.—The illness for the first six days of his stay in the hospital pursued the course of a severe migrating pneumonia, there being involved in succession the right upper, right lower and left lower lobes. The temperature varied between 101 and 104. Most of the time the pulse was between 115 and 130. The respiration rose gradually from 25 to 60 a minute. The mental condition became one of extreme restlessness. The bowel movements changed from a yellowish or brownish semi-solid to a liquid greenish character on February 17. During the first five days after admission he did not vomit.

On February 15 I showed the patient in clinic and a careful examination was made, not only of the chest, but of the abdomen as well, and nothing out of the way was noted as to the stomach by external examination. Treatment consisted of five grains of ammonium carbonate every four hours. On February 17 one-half ounce of whisky was ordered to be given every four hours. One dose of calomel (gr. 1) and soda was given February 17, when the stools had become so loose and frequent.

On the morning of February 18, the ninth day of the disease, I regarded him as a very sick pneumonic patient, but yet one who had a fair chance of passing through the crisis which could be looked for soon. The right upper lobe was already beginning to show signs of resolution.

That afternoon at 5 o'clock he vomited—I copy the record of the nurse—yellow fluid. At 5:30, half an hour later, he vomited dark brown fluid. At 6:30 p. m. he vomited about a pint of black fluid. At 7:15 p. m. he vomited a cupful of black fluid. He vomited repeatedly during that night, each time ejecting the black fluid and on several occasions as much as a pint. He became restless, extremely thirsty and very weak. Water was given in small amounts, digitalin and strychnin were administered hypodermically, and normal salt solution was given by rectum.

At 8:30 a. m., February 19, three pints of salt solution were injected under the skin. When I saw the patient an hour or two later he was quiet, had a fairly good pulse of 120, a rectal temperature of 102°, the breathing had gone down from 60 to 50, he had not vomited for two hours, and I hoped this was the beginning of the critical improvement.

In the evening, however, when I again saw him, his condition was decidedly more alarming. While temperature (101°) and respiration (44) were better, his pulse was of poorer quality, his countenance was sunken and haggard, he was semi-delirious and seemed profoundly shocked and toxic. He had again vomited the dark grumous material and his abdomen had become markedly distended.

1. Campbell Thomson: "Acute Dilatation of the Stomach," New York, 1902. Also the review of the subject by Neck: "Die Akute Magenverwöterung (Sammel-referat)." Centralbl. f. d. Grenz. d. med. u. Chir., vol. VII, No. 14 et seq. Extensive bibliographies are to be found in each of these articles.

An examination of the chest revealed the pneumonic areas clearing. The heart, while weak, was not dilated. The abdomen was greatly distended, very slightly tender on palpation, resonant, except in the flanks; a faint peristaltic wave occasionally passed from left to right. On tapping to test for fluctuation I was surprised to get it with a distinct slap of the wave against the hand, and there was a splashing sound that was plainly heard with the ear near to the body when the patient was shaken, and that sounded, when the stethoscope was placed over the abdomen, exactly like the echoing succussion of hydro-pneumothorax. The fluid shifted readily, as shown by change of position of the patient.

Treatment.—Feeling sure we were dealing with an acute gastric dilatation, I turned the patient on his side, not daring to have him sit up in his weak condition, passed the stomach tube and removed about a quart of dark grumous liquid. The stomach was washed until the water returned clear. The patient seemed much relieved and the vomiting ceased. The stomach as mapped out at this time extended to within one inch of the symphysis pubis; the lesser curvature was two inches above the umbilicus. All food was stopped by the mouth and nutrient enemata were given. Gastric lavage was practiced three times in every twenty-four hours; strychnin and digitalin were given hypodermically; normal salt solution was given by rectum and hypodermically. A firm abdominal binder, with a large pad of cotton, was applied in such a way as to press the stomach upward and away from the lower abdomen. The patient did not vomit after the first lavage; the material washed from the stomach gradually became less in amount and lost its dark greenish look, but for several days the general condition resembled one of profound toxemia with extreme prostration.

He was at times delirious and the evacuations were involuntary. It became impossible on the third day to feed him by the bowel, because of failure to retain the enemata, and rice water in small amounts (3ss-iii) was given cautiously by the mouth. This was retained. Albumin water and milk were later given in small amounts. The record for February 22 is as follows: "The lungs show advancing resolution. Stomach tube passed and about 600 c.c. of bright green fluid obtained. Lavage. Distended with air, the lesser curvature is three fingers above the umbilicus; the greater, one hand's breadth below. Tongue heavily coated; eyes bleary and sunken; mind wandering; pulse regular, fairly full; heart tones strong. Leg, of which patient complains, negative; no thrombophlebitis to be made out."

At this time small, loose, greenish stools were passed two to five times a day. The record of February 25 shows: "The mind clearer; tongue less dry. Right lower lobe nearly clear; right upper seems slow in clearing, is still quite dull; respiration harsh; many coarse, moist râles. The same coarse râles are heard over the left lower lobe, though there is little dullness here. The pulse is quick to-day. Sputa yellow, viscid, slightly offensive, an occasional rusty streak. Stomach outlines as on February 22."

February 28: "On percussion stomach seems to reach one-half inch below umbilicus. Lesser curvature higher than before."

March 8: "Urine 2,400 c.c., specific gravity 1010, no albumin, no casts."

Result.—More and more food was gradually allowed, and the slow but steady improvement was uninterrupted. When the patient left the hospital, March 16, his stomach was about normal in size, but still showed a distinct prolapse. When heard from a few months later from his home in Maryland he reported himself as feeling entirely well.

Remarks.—An analysis of the stomach contents obtained February 19 showed them to be thin, of dark greenish color and containing many fine shreds. There was a faint acid reaction to litmus. Congo-red showed no change. Total acidity was 18; no free H. Cl. No lactic acid. Bile present. No mucus, pus, erythrocytes or leucocytes. Some starch granules; considerable fat. Many short bacilli. On February 22, one and one-half hours after taking milk, an analysis showed dark greenish fluid containing a few curds. Litmus, slightly acid. Congo-red, no change. Tüpfers reagent, no change. Total acidity, 20. Bile present. No blood or pus.

A second case of acute dilatation of the stomach was seen several times with a surgical colleague, in whose practice it occurred and who has kindly furnished me notes of the case.

CASE 2.—A woman, aged 55, weighing about 130 pounds, mother of several children, had had for nine years, with varying frequency and severity, attacks of colic, evidently due to gallstones. She had never been jaundiced.

Operation.—Operation was performed Oct. 20, 1904; the gall-bladder with 142 stones was removed. A rubber drainage tube packed with gauze was introduced into the wound. The common duct was not touched, further than to assure the operator of the non-existence of common-duct stones. At the same sitting a diastasis of the abdominal recti muscles was relieved by freshening the edges of the muscles and uniting them by sutures. It was noted by the operator that the stomach was in its usual position and was not larger than normal, and the region of the pylorus and duodenum was examined for the presence of adhesions, but none was found. The patient left the operating table in fairly good condition. Nine ounces of ether were used for anesthesia, which lasted one hour and thirty-five minutes. Nitrous oxide gas was used at the very beginning.

Postoperative History.—For about twelve hours after the operation the patient, who had promptly regained consciousness, complained of pain in the abdomen and vomited often, each time bringing up a small amount of light greenish liquid. The vomiting then ceased for twelve hours. Then, with complaint of more pain with increase in pulse rate to 158 and evidence of great prostration, vomiting began again, the vomitus now being a dark-brown liquid. The patient's eyes were sunken, the tongue dry, voice feeble and husky. There was *fetor ex ore*. The pulse was small and feeble, the temperature ranging from 99 to 101°. The abdomen was distended; tender only near the wounds. The stomach outlines were clearly made out, showing the greater curvature half way between the umbilicus and symphysis pubis. A succussion sound was plainly heard and the splash of the fluid could be felt below the umbilicus.

Under gastric lavage, rectal feeding, hypodermoclysis and stimulants, there was marked improvement, lasting three days. The tube and nearly all the gauze had been removed, but on October 29 she again became very restless, was nauseated, complained of increased pain and vomited a quart of thick, blackish, offensive material. The pulse rose to 138; the prostration became extreme. In spite of lavage, stimulants, use of salt solution by rectum and hypodermically, she gradually failed and died November 3, fourteen days after the operation. No autopsy was permitted.

Remarks.—The stomach contents, analyzed several days before operation and after the occurrence of the acute dilatation, never contained any free HCl except once, when the acid was being given by the mouth. After a test breakfast, October 18, there was a total acidity of 8. A full meal used as a test for motor insufficiency showed, October 17 and October 20, no retention. After seven hours but 5 c.c. of contents could be obtained. The stomach contents after dilatation occurred showed (e. g., test of October 30) a dark, greenish-black fluid of foul odor, specific gravity 1020. The reaction was alkaline. No blood or bile could be found by chemical tests. A few red cells and leucocytes with much mucus and some epithelial cells were found on microscopic examination. No Oppler-Boas bacilli were found, but there were myriads of other microorganisms of various forms.

In this case the possibility of acute obstruction at the pylorus or the duodenum was thought of, but the removal of the tube and packing gave no relief, and there was a lack of peristalsis such as one would expect with such an obstructive dilatation. It is to be noted that ether and not chloroform was the anesthetic in this instance. In most respects this case resembles the other recorded postoperative cases. The pain, prostration, vomiting of large amounts of dark fluid, the great size of the stomach, the temporary improvement for three days and death in the second week are all as in most other reports of the same accident.

SYMPTOMS.

Comparing these two cases with others that have been reported, they are found as regards *symptoms* to be typical in most respects. The onset of acute dilatation is sudden. There may be complaint of pain or discomfort in the abdomen. This pain may be severe. The vomiting is quite characteristic, brown, grayish, greenish or black, large in amount, and may be offensive. It seems almost to run out of the patient's mouth rather than to be forcibly ejected. Henry Morris says that it comes up in "large gulps without straining." The urine is scanty; the bowels loose or constipated. The temperature is often subnormal, the skin cold and clammy, the pulse small and rapid, thirst is extreme; in short, there is the picture of collapse.

The abdomen, especially the lower half, is distended, though it may be flat if the stomach be well emptied for the time being through free vomiting. Peristalsis, even slight as in my first case, has been rarely reported, an argument advanced by some to disprove the theory of pyloric or duodenal obstruction as a causative factor. The percussion note is drum-like over the gas-containing part of the viscus and flat over the fluid. Fluctuation and the succussion sound are clearly made out, the stomach tube withdraws a large amount, sometimes several pints, of brownish, greenish or blackish, rather thin or gruelly fluid. This fluid generally contains bile, perhaps pancreatic juice and some altered blood. Free HCl, as a rule, is lacking; lactic acid has been found several times. The odor is often offensive, almost never feculent. The gas that escapes through the tube or by belching is often abundant and may be of foul odor. H₂S has been found in it in one or two instances. The stomach, with or without the aid of distension by air injected through the tube, can be outlined as greatly enlarged, extending "even to the symphysis" or "filling the entire abdomen from diaphragm to symphysis." The abdomen flattens in contour as the fluid and gas are withdrawn by the tube.

DIAGNOSIS.

Diagnosis is not as easy as one might think. Peritonitis, either general or local, intestinal obstruction, pancreatic cyst, uremia, postanesthetic vomiting, acute pancreatitis are all to be considered. Of especial value in diagnosis is the succussion sound, and the examination by the stomach tube revealing the characteristic fluid and the enormous size of the stomach. Diagnosis in one case was made when an exploratory puncture through the abdominal wall for suspected pus, the result of the supposed peritonitis, revealed the greenish stomach contents. The writer in this case explains the failure to recognize the existence of dilatation by the simple signs of fluctuation and succussion as due to the fact that, through fear of breaking up possibly existing recent adhesions, he did not dare shake the patient, etc. This sounds much like an *ex post facto* reasoning. Surely a palpation and percussion of the abdomen sufficient to test for fluctuation, or a shaking of the patient, or, better still, of the bed, to bring out succussion is a far safer and a more rational procedure than an exploratory puncture for suspected appendicular abscess or localized peritoneal exudate from other causes.

PROGNOSIS.

An extremely small number of the recognized cases have recovered. I believe my case is the first reported case of recovery in which acute dilatation has complicated pneumonia or pleurisy.

Thomson refers to seven cases of recovery. I am ac-

quainted with recovery in the practice of a surgical colleague in a case following a gall-bladder operation. As Thomson says, types of more moderate severity probably occur and end in recovery so that the prognosis, if these cases were more accurately recognized, would not be so grave as it is generally supposed to be. Some of the instances of late nausea and vomiting after anesthetics may be due to milder forms of acute dilatation. Death when it occurs may be within the first forty-eight hours or it may be delayed for more than a week. In general the disease runs its fatal course within a week. Relapse may occur, and intermissions of several hours with cessation of vomiting and improvement in symptoms have been several times noted.

TREATMENT.

I feel convinced that treatment in my case saved the life of the patient, even though it was begun late, as the existence of dilatation was not recognized until it had lasted probably twenty-four hours.

Treatment should consist in frequent gastric lavage, saline solution by the bowel and under the skin, nutrient enemata, strychnin and other stimulants hypodermically. Box and Wallace advise the use of atropin. This has been found of service in certain cases of ileus, and the resemblance of acute gastric dilatation to dynamic ileus might suggest similar treatment. Change of posture to the right or to the abdominal decubitus should be tried to relieve the possible drag of the mesenteric vessels on the duodenum or the pressure of the overloaded stomach on the same portion of the bowel. I tried a snug abdominal supporter with a large firm pad of cotton, binding it on in such a way as to push the abdominal wall and, with it, the stomach upward in the same manner that the binder is used in cases of enteroptosis. How much this accomplished it is hard to say, but it apparently helped to keep the displaced organ more nearly in its proper place. It has since occurred to me that possibly the stomach might be induced to contract by the application of ice to the abdominal wall or of hot water or even hot air put into the stomach through the tube in the same way that the inert uterus after confinement can be induced to contract through these means. It would seem to be a means of treatment worth trying. That the stomach wall has not entirely lost its elasticity and contractility has been shown by its prompt shrinking on the escape of gas when pricked postmortem, as well as by the same contraction in the wall when at operation in a few cases the stomach has been opened and emptied of its gas and fluid. Surgery—gastrojejunostomy—is advocated by Mayo Robson in intractable cases, when on opening the abdomen it is seen that there is no possibility of correcting the displacement of the viscus and in this way favoring a cure.

ETIOLOGY.

Certain statistical facts can be stated concerning the etiology of this condition. It is commonest between the ages of 20 and 30. A small number have followed trauma. A surgical operation has preceded about one-quarter to one-third of the cases, and a rather strikingly large percentage of these operations has been on the gall bladder or bile ducts. The anesthetic has nearly always been chloroform. Neek saw dilatation follow a small dose of veronal. In some instances overloading the stomach is assigned as the cause—dilatation *ab ingestis*. For instance, Hoffmann² reports the case

² E. Hoffmann: *Munch. med. Wochts.*, vol. II, No. 45, Nov. 8, 1904.

of a male, aged 18, who was a hearty eater and who bolted his food. After a large meal, including several good-sized pickles, pain and vomiting occurred; on the sixth day ileus with peritonitis and encapsulated exudate was diagnosed. Laparotomy was performed. There was no peritonitis, the stomach was found enormously dilated and, on being opened, six liters of fluid, with pickles, escaped. A. Fraenkel³ reports the case of his own child of 6 who, after eating freely of peas, suffered from a typical acute dilatation, recovering only after six weeks of serious illness.

In a number of cases, some other lesion than the dilatation has been found and is regarded as the cause or at least as a contributing factor. Of Thomson's 44 cases, one was associated with empyema, three with pleurisy and pneumonia and one each with typhoid, scarlet fever and an obscure fever. Brown⁴ saw a case in a choreic girl; A. Fraenkel³ reports a case in an anemic girl with hemorrhage from the stomach. No ulcer, which was suspected, was found, but a long, vertical, dilated stomach. Fraenkel thinks anemia and atony plus food and drink may account for the dilatation.

While, therefore, trauma, surgical operation, overloading of the stomach, preceding or accompanying diseased conditions, are assigned as causes in most cases, in others no cause whatever is recognized as operating and the dilatation might be regarded as idiopathic, i. e., the cause not discovered.

GENERAL REMARKS.

It is not my purpose to speculate as to the exact mode of production of acute dilatation of the stomach nor to review in detail the various theories that have been advanced to explain it. While a number of autopsies have been performed—in most of Thomson's 44 cases postmortem examinations were made—many of them are very incomplete and there is no constant finding save the greatly distended stomach with its contents of gas and fluid and commonly submucous hemorrhages and erosions. In several instances the dilatation has included not only the stomach, but also that part of the duodenum above the crossing of the superior mesenteric vessels. Only a few microscopic examinations of the wall of the stomach have been made; the nerves, the vagi and splanchnic, have been practically overlooked; bacteriologic and chemical examinations of blood and stomach contents are scanty; only occasionally is the condition of the pancreas noted with care, so that one sees that there is much light that might be thrown on the subject by carefully conducted complete autopsies.

More careful observations have been made as to gross conditions that might cause obstruction at the pylorus or in the duodenum. The fact that several cases have followed operations on the bile tract, such a close neighbor of the duodenum, makes one think of the possibility of pressure on this part of the intestine by drainage tube or exudate as a possible cause, or of the extension of inflammation to the duodenal or gastric wall. Albrecht⁵ and others have drawn attention to the pull and pressure of the superior mesenteric vessels on the underlying duodenum, particularly when the small intestines were low in the pelvis and by their dragging weight pulled these vessels taut. Several observers have found, by necropsies and by experiment, evidence sufficient to make them adherents of this theory. Still

others believe that the overloaded stomach itself presses on the duodenum and so really obstructs its own outlet, and the enlarged, overloaded viscus pushes the small intestines downward, increasing the pull on the superior mesenteric vessels and thus still further adding to the obstructive force that is blocking its outlet. We thus have an illustration of the vicious circle of causes so frequently seen in conditions of disease.

Kelling⁶ has advanced an additional theory and he is supported in this by Braun⁷ and Seidel. Kelling bases his belief largely on experimental work on dogs. A simultaneous closure of the duodenum and cardia would result in an overdistension of the stomach and in the accumulation of fluid and gas. A valve-like fold in the lower esophagus opens by active contractions of the gastric musculature. If for any reason, as through inflammation of the wall of the stomach or defective innervation through abnormally acting vagi or other nerves these muscles became incompetent, and at the same time if a kinking of the duodenum were to occur—and Kelling finds that it may—the condition would be ripe for an overdistension and hypersecretion, or more properly a hypertransudation from the wall of the stomach, i. e., the contents could escape through neither pylorus nor cardia. If the kink in the duodenum is below the opening of the common bile duct, bile and pancreatic juice will, of course, be constituents of the gastric fluid. Kussmaul⁸ long ago called attention to these duodenal kinks.

Some adhere to the theory of a sudden toxic paralysis—e. g., through the poison of an infection, local or general, or perhaps chloroform—of the wall of the stomach permitting of abnormal hypersecretion, the accumulation of gas arising from fermentation or expired, as it were, from the vessels in the wall of the stomach (?), the paralysis permitting the yielding of the wall of the viscus and preventing peristalsis vigorous enough to cause the emptying of the organ *per vias naturales*.

To all of these theories there is some objection that can be raised. Either the theories are wrong or acute dilatation of the stomach may arise from more than one cause and thus permit more than one explanation.

It is, perhaps, idle to speculate, yet it seems as though some involvement of the nervous or muscular apparatus of the stomach wall in inflammatory or toxic change must be present to account for the enormous amount of transudate and gas, the great size of the stomach whose walls seem parietic, and for the alarming and too often fatal condition resembling profound toxemia. Mechanically obstructive causes may be operative, as the numerous observations go to show, but that they are primary or that they are the sole causes is not proved.

As I have said, more careful histologic, chemical and bacteriologic examinations are necessary before the pathogenesis of this condition shall be made clear, and more attention should be given by the clinician to noting the condition of the stomach as regards location and size before and during operations and at the beginning of infectious diseases. A previously existing gastroparesis might predispose to acute dilatation. So too, the condition of the stools during these attacks might show whether or not the same peculiar blackish material found in the stomach is present in the lower bowel, and in this way throw some light on the possible presence of duodenal obstruction.

HEAD INJURIES ACCOMPANIED BY INTRACRANIAL HEMORRHAGE.*

RALPH P. PEAIRS, M.D.

MILWAUKEE, WIS.

As house surgeon at the Emergency Hospital, it has been my privilege to see and to attend a large number of head injuries, of which some have been very serious. The attitude of some of our best surgeons regarding early operative interference in these cases has prompted me to write this article, the purpose of which is to bring out a few points in the treatment of head injuries accompanied by intracranial hemorrhage. The point which I wish to emphasize is the necessity of prompt surgical interference under certain conditions and the probable result when the surgeon waits for the development of focal symptoms. As an illustration, I wish to cite three cases which were recently treated at the Emergency Hospital. For these cases I am indebted to Drs. Bading and Reineking attending surgeons to the hospital.

CASE 1.—On Feb. 22, 1905, about 1 p. m., C. A. B., male, aged 27, was brought to the hospital by the police. He was profoundly intoxicated when admitted and it was thought that he had fallen down a flight of stairs, but no definite history was obtained, as the man was a stranger and without friends.

Examination.—This showed a superficial laceration of the scalp about one inch long over the left parietal eminence, a small laceration over the right eye and a slight dilatation of the right pupil, which was uneven and reacted slowly to light. The man's pulse was 62, temperature 97.4 by rectum, respiration 24. He vomited several times soon after entrance.

Hospital Record.—The patient was put to bed for observation. For several hours he was very quiet and the effects of the liquor did not seem to pass away. About 2 a. m. I was called by the nurse, who had noticed a twitching of the muscles of the left hand and forearm, followed by a rigidity of the extremity. Soon afterward the lower extremity on the left side became similarly affected. Later the right side became involved. There were frequent muscular twitchings, followed by a rigidity of the extremities. At 6 a. m. I was again called. The same conditions were present, but were more noticeable. The pulse at this time was 124, temperature 101.6 in the rectum, respirations 36. It was thought that this might be a case of skull fracture with cortical laceration, and an expectant line of treatment was advised. There was a gradual rise in the pulse, temperature and respiration, and during the second night the pulse was as high as 180, temperature 105 in the rectum, respirations 40. On the following morning the man was still completely comatose. He grew gradually worse and died at 3 p. m. February 24, fifty hours after admission, the temperature going above 107, while the pulse could not be counted.

Autopsy.—On the following day a postmortem was held and the findings were as follows: There was a fissured fracture of the skull on the right side, extending from the squamous portion of the temporal bone to the occipital protuberance. There was a rupture of the middle meningeal artery with an immense subdural clot practically covering the right hemisphere.

CASE 2.—C. B., male, aged 32, jumped from a moving street car on the morning of July 14, 1905, and was brought to the hospital at 7:50 a. m.

Examination.—There was a slight laceration over the olecranon process on the right side, and it was to have this wound dressed that he was brought to the hospital. He complained of severe pain in the head and was somewhat dazed. Examination of the head showed a contusion of the scalp over the right parietal eminence, but no abrasion.

Hospital Record.—He was put to bed and his condition rapidly grew worse. He was very restless, complained of pain in the head, vomited, and his pulse became full and slow.

Within six hours he became very restless and delirious; pulse 44, temperature 98.8 by rectum, pupils equal and reacting slowly to light. There was twitching of the muscles of the right upper extremity, followed by rigidity. Twelve hours after admission his pulse was 68, temperature 100.4 in the rectum, respirations 24. There were frequent twitchings of the muscles of the extremities of both sides, followed by rigidity of the same parts, but at no time was there paralysis. During the night he steadily grew worse, and at 3 a. m. on the following morning his pulse was 142, temperature 103.2 by rectum, respirations 47. The respirations were snoring in character and he was becoming cyanotic. His pupils were equal, but sluggish. He was in deep coma, but there was no paralysis, nor were focal symptoms present. It was thought that this was a case of intracranial hemorrhage and that operative interference was indicated. Accordingly the patient was prepared for operation.

Operation and Result.—The question arose as to where the skull should be opened. It was decided to open on the right side, since there was a contusion of the scalp on that side, and if hemorrhage was not present an opening was to be made on the opposite side. An incision was made over the motor area on the right side, and when the skull was exposed a fracture was found. It was not depressed and was about four inches in length, following closely the direction of the squamous suture. A trephine opening was made and an extradural clot was exposed. The opening was enlarged and the bleeding vessel found. It proved to be a posterior branch of the middle meningeal and a ligature was applied. The clot, which was very large, extending over the greater portion of the right hemisphere, was removed. As soon as pressure was relieved the breathing became better and the patient improved rapidly in every way. Even before he left the table the change was noticeable. Within four hours after his removal from the operating room he answered questions and apparently knew what was going on about him, although he had been profoundly unconscious for the preceding eighteen hours. Twenty-four hours after the operation his pulse was 120, temperature 101, respirations 40, and he was perfectly conscious. He made an uneventful recovery.

CASE 3.—On Aug. 28, 1905, at 8:30 a. m., B. H., an Austrian, aged 47, was brought to the hospital from the county jail.

History.—He was able to talk a little, but not rationally, and no definite history could be obtained. It was learned that on the afternoon of August 27 he had been found lying near the street-car track outside of the city limits. The sheriff had been notified and the man was brought to the county jail, where he remained over night.

Examination.—He had the appearance of having been drinking heavily. Examination showed that the left upper extremity was rigid and the forearm flexed to a right angle. The patient did not know whether or not he had been injured, and there was no evidence of any traumatism except two small areas of ecchymosis over the left thigh. His pulse was 48, temperature 99 per rectum, pupils equal.

Hospital Record.—From the above history and symptoms present a positive diagnosis was not made at this time, although the case appeared to be one of intracranial hemorrhage, probably the result of an injury. He was put to bed for observation. On the following day his condition was not so good. The right pupil was slightly dilated, the left upper extremity still remained spastic, and there were frequent twitchings of the muscles which were not present on the preceding day. The lower extremity on the left side had also become rigid. He refused all nourishment, his mental condition was not so good, and he passed both urine and feces involuntarily. At 4 p. m., August 29, his pulse had risen to 80, temperature 100.6 by rectum, respirations 30.

On the second day following his admission his condition had become much worse. His pulse was 104, temperature 102 by rectum, respirations 36. Both the upper and lower extremity on the right side had become rigid, with twitchings of the muscles from time to time. The left side remained in the same condition, but more marked. The man was completely comatose, his respirations stertorous and he was cyanotic.

* Read at the meeting of the Milwaukee County Medical Society, 1906.

Operation.—At this time it was decided that the patient's condition warranted opening the skull, and accordingly he was prepared for the operation. The entire head was shaved, but no evidence of any injury whatever could be found on the scalp.

At 4 p.m. that afternoon he was anesthetized; he required but little anesthetic. An incision was made in the scalp over the motor area on the right side. No fracture was found, and an opening was made in the skull with a trephine. The dura was bulging, but did not pulsate, and when incised a large amount of dark fluid blood escaped. The quantity is not known, but there remained a large cavity, extending almost over the entire hemisphere, and at the opening of the brain was separated about one inch from the skull. Such a quantity of blood would cause great intracranial pressure. There was no active bleeding, nor was any clot present. The cavity was irrigated with salt solution and the wound closed with drainage.

Result.—There was a marked improvement in the character of the respirations immediately following the operation and the cyanosis disappeared. During the night the pulse was 120, temperature 103 in the rectum, respirations 40, and the patient restless. On the following day there was a decrease in the pulse, temperature and respirations, and his mental condition was much improved. He talked freely, but did not seem entirely rational for four days after the operation. He could give no history of any injury, but thought that he had fallen, striking his head. At times he complained of severe pain in the head on the right side and did not want to be disturbed. He remained in the hospital about two weeks and was then transferred to another institution. Unfortunately, an abscess developed within the skull anterior to the opening and prolonged his stay in the hospital, but he made a complete recovery. While it is to be regretted that an infection occurred in this case, yet it is a good illustration of the fact that serious results do not necessarily follow an intracranial infection.

From a study of these three cases which are similar, the one patient treated expectantly, the other two operated on, we can see that the diagnosis of intracranial hemorrhage does not depend on the development of local symptoms. In none of these cases did a hemiplegia occur. Local symptoms are due to a local lesion and extensive compression of the brain does not necessarily produce local symptoms. Park states that when intracranial pressure has reached a certain point epileptiform convulsions result, varying in intensity, affecting all the limbs and terminating perhaps with rigidity, and that such a condition is an expression of high pressure within the cranium. That paralysis does not necessarily follow rupture of the middle meningeal artery is well illustrated by these cases. An article on the diagnosis of hemorrhage from the middle meningeal artery by Dr. C. H. Lemon has appeared in a recent issue of the *Wisconsin Medical Journal*. He dwells on the importance of an early diagnosis and active interference and emphasizes particularly the character of the pulse and respirations. A slow pulse which later becomes rapid and a marked increase in the respirations which become stertorous are the two most important symptoms. In a case with a history of injury to the head and in which the patient is unconscious, if these two symptoms are present, we know that the intracranial pressure is increased. The most probable cause of this increased pressure would be hemorrhage or a depressed fracture. The latter is easily excluded. Usually the patient becomes cyanotic and there is frequently a dilatation of one pupil, but this sign is not reliable. The period of consciousness between the accident and the persistent coma is recognized as a very important symptom of intracranial hemorrhage. In only one of these cases, however, was this symptom distinct.

One point that deserves emphasis is that in all of these cases both sides of the body were similarly involved. It is true that the side opposite the lesion first showed symptoms of irritation, but the same condition was soon present on the other side. In Case 3, no sign of injury could be detected after shaving the entire head, and this case shows clearly that very serious damage may occur within the skull with absolutely no evidence of external injury. For several days this man's friends could not be located, as he had given another name on admission to the hospital, and when they were found they knew nothing regarding the case except that he had been missing for several days. In this respect, the case is unusual, as in almost every case some history of the patient can be obtained. In this case the diagnosis was based chiefly on two symptoms, a slow pulse and the spastic condition of the arm. The one indicative of pressure, the other of irritation.

As regards treatment the question arises, when should an operation be advised? In looking over the textbooks on general surgery I find that they nearly all state that operative interference should not be undertaken until focal symptoms develop. This, I believe, is wrong. That focal symptoms do not always develop is clearly shown by these three cases. If the hemorrhage is small and is confined to the motor area local symptoms will probably develop, but if the hemorrhage is large these symptoms may be absent. One point which I wish to emphasize is that the absence of focal symptoms does not mean that hemorrhage is not present. It is largely due to the absence of focal symptoms, I think, that an early positive diagnosis is not made in such cases. I believe that an operation is indicated when there is a history of injury to the head followed by loss of consciousness, if the patient has a persistent slow pulse, that is one of fifty or under, later becoming rapid, and is gradually growing worse. Certainly there is less danger to such a patient in trephining the skull than in treating him expectantly. This statement is borne out by statistics. Weisman collected 257 cases. Of these 147 were treated expectantly, with 131 deaths, while of 110 cases in which operation was performed only 30 died. Von Bergman cites 143 cases treated expectantly, in only 12 of which the patients recovered, a mortality of over 90 per cent. With these figures before them, I can not understand why many of our best surgeons hesitate about operating in such cases. Certainly these men would not hesitate about doing an appendectomy, but would urge it if the case were an acute one. They would not hesitate regarding an exploratory laparotomy for diagnostic purposes; why, then, should they delay trephining the skull for the same purpose if the patient is in danger? Under aseptic conditions, the chances of infection following trephining are certainly no greater than following a laparotomy, and yet the surgeon who would urge this operation hesitates when the question arises of opening the skull. No doubt a number of these patients will die whether operated on or not, but I believe that many more could be saved by prompt surgical means.

Park cites a case in which Parker, in 1877, opened the skull for hemorrhage and, not finding it, opened on the opposite side, removing a large clot, and saw his patient restored to health. To use his own words, "this was considered a very bold procedure," but if we had more men of like mind to-day many patients could be saved who otherwise would die of neglect.

THE NEURONS.*

LEWELLYS F. BARKER, M.D.

Professor of the Principles and Practice of Medicine, Johns Hopkins University; Physician-in-Chief to the Johns Hopkins Hospital.

BALTIMORE.

I. INTRODUCTION.

I have been invited to speak on the subject of "The Neurons" and to outline to you the present state of knowledge concerning them. No topic has led to more animated discussion, perhaps, during the past ten years. Indeed, the word "neuron," which sprang so immediately into vogue after its introduction by Waldeyer in 1891, appears to have excited, by virtue of its rapid and widespread popularity, a feeling of bitter hostility, of unrelenting antagonism in certain circles. Hailed at its advent as the simplifier and revolutionist of our knowledge of the nervous system, and enthusiastically adopted by teachers of anatomy, physiology and pathology, the neuron doctrine has in subsequent years been subjected to the fiercest of assaults; not only has the truth of its tenets been questioned; its adversaries even go so far as to designate it as "a real danger to science."

The neurohistologic world appears to be divided into two camps, that of the neuronists and that of the antineuronists. The controversy, curiously enough, has been a rather one-sided affair, though by no means wholly so. The so-called "neuronists" have spoken and written of the nervous system as a mass of nerve units or neurons and have devoted themselves chiefly to observations and experiments concerning the internal and external morphology of these units, their relations to one another, and especially their arrangements in chains and groups, and the relations of such chains and groups to function in health and in disease. With few exceptions they have refrained from controversy on the hypothetical side. The so-called antineuronists, on the other hand, while they have made some admirable contributions to real knowledge, have devoted a remarkable amount of time and energy to polemical writing; one of them is the author of a book of nearly 500 pages in which few new facts, if any, are brought forward, the whole volume being given over to a condemnation of the neuron doctrine and a denunciatory arraignment of its supporters. In the writings of the antineuronists such statements as "the neuron theory must be abandoned," "the neuron theory can no longer be held," "the neuron doctrine is false through and through," "ueber der Neurontheorie der Stab gebrochen ist" are reiterated monotonously. That the argument has become very heated at times is shown by some sample statements which I select at random from the writings of the controversialists. One of them refers to the neuronists as the "Golgi band"; another antineuronist belittles the work of a great investigator who denies networks of extracellular neurofibrils between the neurons in leeches by stating that his results are due "wholly, certainly, to the incompleteness of his preparations"; to this a neuronist has replied that "such an expression is not only very conceited, but also very partisan and juvenile." Another strong opponent of the neuron doctrine speaks of the period since when "the ominous neuron theory has animated only those who are biased." Still another remarks that "no one with normal vision can escape the

convincing impression of Apathy's specimens, provided his eye is not dimmed by envy or injured vanity." And, finally, though I could weary you with examples, Nissl states that Ramón y Cajal "is not competent to pass judgment on histologic questions," an opinion perhaps influenced by Ramón y Cajal's criticism of Nissl's "nervous gray," which he declares to be nothing but a "very cheap anatomic-physiologic conjecture, which contradicts everything that the most convincing methods teach us of detail."

From controversial statements such as these only one thing is clear, namely, that those who have made them are quarreling about matters of opinion more than about matters of fact. There is no reason why bitter dispute should long continue over easily verifiable fact. Experience teaches, however, that it is those opinions which are most feebly founded in fact and are least capable of proof that mankind is prone most passionately to defend. Science ought to try to avoid controversy by emphasizing facts and by properly estimating hypotheses. Further, scientific men should know that, once involved in discussion, nothing is gained by the bandying about of personalities; on the contrary, confidence is inspired by simple honesty in work, fairness to adversaries, moderation in statement and dignity in utterance. That was a homely but sensible saying of Truthful James when he declared that:

"I hold it is not decent for a scientific gent

To say another is an ass—at least, to all intent;

Nor should the individual who happens to be meant

Reply by heaving rocks at him, to any great extent."

As Mr. Brander Matthews says, in his recent admirable essay entitled "Persuasion and Controversy," in reference to convincing the public, "It is not really argument which is effective; it is information." Give the medical profession a plain statement of fact, even in a technical field, and it will decide for itself. Not that discussion is unnecessary; quite the contrary. Criticism is essential to progress. As Schiller said to the thinkers and workers of his day, "Let there be strife among you, and the union will come quickly."

In 1899, in my book on the "Nervous System and Its Constituent Neurons," I tried to give an unprejudiced account of the state of knowledge at the time regarding the finer structure of the nervous system. Since then, despite the polemical activity which has prevailed, I have refrained from writing or speaking on the subject. Now, that new methods have been devised and some important new facts have been discovered, the time has come when I welcome the opportunity of reviewing once more, very briefly, the actual advances which have been made. I shall attempt, then, to-night, to pierce the dense cloud of controversial smoke which overhangs the whole neuron area in order to make as clearly visible as possible the little tongues of flame of real research hidden there. Two of these tongues are leaping high, and many think that they are likely speedily to convert the smouldering smudge of conflicting hypotheses into a brilliant blaze of fact. Ramón y Cajal lighted one of them in 1903; Ross Granville Harrison lighted the other in 1904. We shall examine them both along with other illuminating influences a little later.

II. ORIGIN OF THE NEURON CONCEPT: FACT AND THEORY IN 1891.

You are doubtless so familiar with the origin of the neuron concept that mere mention of the main factors will recall the whole story to your minds. It will be remembered that, after the nerve fibers and the so-

* An address delivered by invitation before the Harvey Society of New York.

* The author prefers the spelling "neurone" for the reasons given in his article on "Neurological Nomenclature," Johns Hopkins Hosp. Bull., 1896.

called nerve cells were discovered, there was long great doubt as to the exact relations of these histologic elements to one another. Wagner, in 1851, and Deiters, in 1864, had made it probable that of the many processes of a multipolar ganglion cell in the anterior horns of the spinal cord only one was directly related to a nerve fiber. In 1871 Gerlach had shown that the fibers of the posterior roots do not represent processes of nerve cells of the posterior horns, but that on entering the posterior horns they divide and subdivide until they exhaust themselves and are lost in the gray matter. The question of the relation of the sensory fibers to the motor cells of the anterior horns, so important in connection with the reflexes, remained, therefore, the subject of conjecture; Gerlach advanced the hypothesis that a continuous nerve network exists throughout the gray matter of the whole central nervous system, and that all nerve cells and all nerve fibers are thus connected with one another, a hypothesis which met with almost universal acceptance among anatomists and physiologists for the next fifteen years.

In 1886 the distinguished embryologist, Wilhelm His, began to publish his careful researches on the embryology of the nervous system. He stated in his papers that every nerve fiber is a process of an embryonic nerve cell (neuroblast); that, besides the process of the neuroblast, which becomes later the axis cylinder of a nerve fiber, other so-called protoplasmic processes (dendrites) grow out; that the single nerve cells wander for considerable distances during their development from the site of their origin; that the posterior roots of the spinal nerves are the axis cylinder processes of the spinal ganglion cells which grow into the cord, and that the anterior roots of the spinal nerves are outgrowths of axones of anterior horn cells, these outgrowths becoming subsequently covered by extracentral neurilemma cells. Most important was his idea that every nerve cell with its axis cylinder process and protoplasmic processes is a single cell, separate at the beginning from all other cells and from any end organ; connections with other nerve cells or with any end organ, like muscle or gland, His declared, either do not exist at all or, if they exist, arise secondarily. Embryology and embryologists were not so highly valued in 1886 by the rank and file of anatomists and physiologists as they are to-day, and His' remarkable studies made but little impression on the strongly held hypothesis of Gerlach. As a result of pathologic anatomic considerations, especially those bearing on experimental degenerations and the resulting sharply circumscribed areas of degeneration, Forel, in 1887, came to conclusions similar to those of His and opposed to those of Gerlach and the dominant school of the day.

It was not, however, until 1888, when Ramón y Cajal began to make his striking publications of results obtained by the then little-known method of Golgi applied to the study of the embryonic nervous system, that the histologic world became convinced of the value of the ideas of His and Forel. Stroke after stroke of confirmation with the method of Golgi, which put a delicate black crust of silver over the outside of the nerve cell and each one of its processes, no matter how delicate, followed in different parts of the world. von Kölliker, von Lenhossek and Edinger in Germany, van Gehuchten in Belgium, Retzius in Sweden, Schafer in England, Berkeley, Starr, Strong and others in America, repeated and extended the researches of Ramón y Cajal. Though the method is applicable satisfactorily only to embryonic

tissues, its results were confirmed, in the main, especially by Dogiel and Retzius, in the tissues of the adult by the method of Ehrlich.

By the use of these two methods a newly recognized anatomic unit stood out, clearly visible in the tissues. To call it nerve cell was a little confusing, as that term had already been applied to the cell body in the gray matter independent of the related axis cylinder process. This unit included not only the old nerve cell with its dendrites, but also its axis cylinder process and all the collateral and terminal ramifications of the latter. Waldeyer¹ suggested that it be called neuron, a name which speedily found its way in all languages, including our own. Waldeyer's article, an admirable collective review of the researches in histology, embryology and pathology, undoubtedly had great influence in quickly popularizing the neuron conception. A definite anatomic fact had been established, viz., the possibility of demonstrating in embryonic tissues by Golgi's method, and in adult tissues by Ehrlich's method, a hitherto nondemonstrable unit in anatomic structure. On the basis of embryologic and pathologic work which was brought into relation with this fact, a body of doctrines, often called the neuron doctrine, was built up. A sharp distinction between the *fact* and the associated *doctrine* should be borne in mind, for much of the subsequent dispute has been due to neglect in this regard.

The associated neuron doctrine included a number of statements which at the time could be regarded as possibilities only, not as established facts. As it was formulated, it may be summarized somewhat as follows: A diffuse nerve network, in the sense of Gerlach, does not exist. There is no nerve fiber independent of a nerve cell; every nerve fiber, no matter where situated, is to be regarded as the process of a nerve cell. A nerve cell with all its prolongations (dendrites and axon) constitutes a nerve unit or neuron. These nerve units are independent of one another. They are related to one another histologically and physiologically, not by continuity, but by contact; they are not united with one another anatomically or genetically. The whole of the nervous system, exclusive of blood vessels, glia and ependyma, consists of nerve units or neurons superimposed on one another. The neurons are so arranged that a nerve impulse in a given neuron always follows in one direction; it passes from the dendrites to the cell body, from the cell body to the axis cylinder process and thence to the dendrites of another neuron. All parts of a neuron are dependent on the nutritive influence of the nucleus of the cell body. The whole neuron, axon, as well as cell body, is derived from a single body cell. When a nerve fiber degenerates as a result of severance of connection with the cell body, regeneration of the axis cylinder takes place by outgrowth from the central end—see the mass of doctrines and hypotheses clinging by their tendrils to the supporting pole of anatomic fact! Here we have not only the neuron which everybody can see who looks for it, but several neuron theories which were still more or less speculative, including (1) the Cellular or Neuroblast Theory, (2) the Theory of Regeneration of the Peripheral Axon Solely by Outgrowth from the Central End, (3) the Contact Theory, (4) the Theory Denying Extraneuronal Nervous Structures, and (5) the Theory of Dynamic Polarity of the Neurons.

III. THE DISCOVERY OF THE NEUROFIBRILS: FACT AND THEORY IN 1899.

I choose 1899 as the next date of summary, for in the first place it was between 1891 and 1899 that the studies of Apáthy, Held and Bethe began to attract widespread attention and the theories of Nissl to excite comment:

Fig. 1. Apáthy's schematic representation of the course and connections of the conducting paths in a transverse section of the somite of the leech. (After S. Apáthy, *Mitt. a. d. Zool. Station zu Neapel*, 1897, vol. xii, plate 32, Fig. 6).

Fig. 2. Part of the network around a cell in Bethe's nucleus. The paler network is the Golgi net. Held believed that the thick endings in the network correspond to his "end-feet." He believed that the axons helped to form this network. Recent investigations do not corroborate this view. The Golgi net is now believed by Held himself to be glia. (After H. Held, 1897).

moreover, at the end of that year I summarized in a special volume the facts and theories bearing on the neuron up to the date of its publication.

The Hungarian histologist, S. Apáthy,² by a difficult method depending on the use of a special variety of gold chloride, succeeded in demonstrating in the ganglion cells of various invertebrates, especially the leech, remarkable appearances of fine lines, and, in places, of networks formed by anastomosis of these lines with one another. This discovery of Apáthy is an admirable advance; it has since been manifoldly confirmed and will always stand to his credit. Confronted by such a remarkable histologic picture as the fibrils presented, he immediately began to speculate about them and advanced the following hypotheses:

(1) The neurofibrils in the nerve fibers and in the

Fig. 3.—Cell from the ventral horn of the lumbar cord of an adult rabbit, showing masses of neurosomes in the "end-feet" terminating on the dendrites and cell body. (After H. Held, 1897).

nerve cells are the especial conducting element of the nervous system.

(2) There are two kinds of cells in the nervous system—"nerve cells" and "ganglion cells"; the function of the former is to build neurofibrils which grow into and through the latter, a single neurofibril passing continuously through a series of ganglion cells.

(3) In the so-called "point substance" of Leydig, in invertebrates, neurofibrils leave the nerve fibers and nerve cells and give rise to free extracellular networks of neurofibrils (Fig. 1).

Fig. 4. Ganglion cells with fibrils stained by Bethe's method. A, human anterior horn cell of man; B, cell from nucleus of facial nerve of rabbit, Nissl's bodies also shown; C, dendrite of a human anterior horn cell; D, two human pyramidal cells. (After Bethe, 1900). Bethe's method showed isolated fibrils, but was not delicate enough to show the anastomoses among the fibrils.

² Apáthy, S.: "Das leitende Element des Nervensystems und seine topographischen Beziehungen zu den Zellen." *Mitttheil. a. d. Zool. Station zu Neapel*, 1897, vol. xii, pp. 195 to 718.

Subsequent researches have not supported these hypotheses; indeed, the weight of recent research tends to discredit them all.

The studies of H. Held³ of Leipzig took a somewhat different direction. Golgi's method had revealed around the cell bodies of neurons (1) a pericellular network which Golgi himself believed to consist of neurokeratin and (2) a pericellular plexus of the fine terminal fibers of the axons and collaterals of other neurons. Some have thought that this plexus of fine terminal fibers formed an anastomosing network—a real "pericellular net"; others have declared that the individual fibers interlaced, but did not anastomose. Held studied these pericellular structures by various histologic methods and found that the terminals of nerve fibers end in delicate expansions—so-called "end-feet" (*Endfüsse*)—recognizable by the large number of minute neurosomes which they contain on the surface of the cell body and its dendrites, fusing, he believed, by actual concrescence, with the protoplasm. He saw, he believed, delicate connections of these "end-feet" with one another in the form of an anastomosing network, so that he advanced the idea of two kinds of interneuronal connection, (1) anastomosis of the terminals of axons derived from different neurons in a pericellular network (Fig. 2) and (2) direct continuity of the protoplasm of the end-feet with the protoplasm of the cell to which they are attached (Fig. 3).

Next in order came the researches of Bethe.⁴ Everyone who had tried Apáthy's method of staining neurofibrils had failed with it, and when Bethe announced his discovery of an easier method of demonstrating them it was gladly welcomed. The method had

the advantage, further, of staining the neurofibrils in vertebrates, including man. His method showed, he asserted, independent, non-anastomosing neurofibrils running through the cell body or passing from one dendrite to another without passing through the body of the cell (Fig. 4). He regarded the neurofibrils as the sole conducting element in the nervous system. His method showed also a pericellular network which he called the "Golgi net." It seemed to Bethe probable that this Golgi net was the medium of communication between the neurofibrils of the nerve fibers terminating about the cell and the neurofibrils inside the cell; according to this

hypothesis the neurofibrils would represent a continuous conduction system throughout the whole nervous system, the so-called neurons representing, as it were, a bed in which the essential neurofibrils lie.

In 1898 F. Nissl⁵ launched his hypothesis (more fully developed in 1903) of the structure of the gray matter. He called attention to how little is really known about the gray matter, information yielded by Golgi's method not being regarded as of any value. Nerve fibers we know and nerve cells we know, but in the gray matter there must be something specific which is a mystery. This mystery he designates *nervröse Gran*, or "nervous gray." He lays great stress on the Golgi nets around the nerve cells; he asserts that histologic methods leave us in the lurch when we seek to follow axis cylinders into the gray matter beyond the point where the myelin sheaths cease.

There is thus an area around nerve cells and between them and the medullated nerve fibers which is filled up with "nervous gray," for him the most important constituent of the whole nervous system. While this is all we really know, Nissl says, still we must suppose that this nervous gray is so constructed that it conducts nerve impulses and permits the reciprocal action of the elements of the nervous tissues on one another.

Fig. 5. Nissl's scheme of the "nervous gray." The left half of the scheme shows the facts as known according to Nissl. In the right half Nissl's hypothesis of the structure of the nervous gray is illustrated.

3. Held, H.: "Beiträge zur Struktur der Nervenzellen und ihrer Fortsätze," Arch. f. Anat. u. Entwicklsgesch., Leipzig, 1897, pp. 204 to 294; also, Supplement volume, 1897, pp. 273 to 312.

4. Bethe, A.: "Über die Primärdendriten in den Ganglienzellen von Menschen und anderen Wirbeltieren," Morphol. Arch., 1897, vol. xvi, pp. 95 to 116; also "Über die Neurofibrillen in den Ganglienzellen von Wirbeltieren und ihre Beziehungen zu den Golginetzen," Arch. f. mikr. Anat., Bonn, 1900, vol. iv, pp. 513 to 558.

5. Nissl, F.: "Nervenzellen und graue Substanz," Münch. med. system., Leipzig, 1903, pp. 1 to 488.

He has devised a most extraordinary hypothesis to account for this function of the "nervous gray." Like Bethe's theory, it involves the communication of the neurofibrils in the nerve cells by way of the Golgi nets with a great complex of neurofibrils outside the Golgi nets (Fig. 5).

Fig. 6.—Large and medium-sized pyramidal cells from the human visual cortex. *a*, Axis cylinder. (After Ramón y Cajal, 1906.)

Thus far knowledge and theory had advanced by 1899, and in my book, and in an article entitled "The Validity of the Neuron Doctrine," published in that

Fig. 7. Funicular cells from a rabbit fifteen days old. *A*, large cell; *B*, small cell; *a*, large neurofibrils ramifying in the perinuclear network; *b*, fine neurofibrils continuous with the cortical network; *c*, *d*, neurofibrils bifurcating on their arrival at a large dendritic trunk. (After Ramón y Cajal, 1906.)

year, I called attention to these phases of the subject, advised active skepticism as regards the new hypotheses of Apáthy, Bethe and Nissl, and expressed the opinion that, even if the neurofibrils really represent a constant

constituent of the nerve elements, and even if the inter-neuronal relation be a more intimate one than that of mere contact or contiguity, the essential feature of the neuron conception remains unaltered, Waldeyer having

Fig. 8. Large funicular cell from a rabbit eight days old. Certain only of the primary neurofibrils have been drawn. The network formed by the anastomoses of these filaments is well shown *a*, neurofibrils terminating in the network; *b*, primary neurofibril running through. (After Ramón y Cajal, 1906.)

stated in an article in which he gave the neuron its name that "if we assume . . . the existence of nerve networks, the conception is somewhat modified, but we

can still retain the nerve units. The limits between two nerve units would then always lie in a nerve network and not, anatomically at least, be exactly definable with our present methods." I accompanied my review, therefore, at that time, with the statement, "There may be

important that we should find out all that there is to learn about them; but that the human body is made up largely of a mass of cells, and that the human nervous system is made up largely of great numbers of cell units, the so-called neurons, would seem to be facts too firmly established ever utterly to be overthrown."

IV. MORE RECENT WORK: FACT AND THEORY TO-DAY.

During the next five years (1899-1904) the subject of neuro histology was enriched by a mass of detailed

Fig. 11.—Scheme of the course of the neurofibrils in the nervous systems of worms. *G*, ganglion; *Gz*, ganglion cells; *Rz*, reception cells. (After Bethe, 1903.) Not confirmed by recent researches.

investigative work.⁶ Many studied the neurofibrils and extended our knowledge of them, among them Paton, Prentice and Blart in America. In addition, the

units smaller than cells, and in all probability there are; there may be, and probably are, in the nervous system units other than those generally described, and it is

period of polemical writing on the neuron and the neuron doctrines reached its zenith. Edinger, in 1898, had urged the importance of the concept of the neuron

⁶ See the review by Prof. G. E. Goghill, "Recent Studies on the Finer Structures of the Nerve Cell," *Jour. Comp. Neurol.*, Granville, O., 1904, vol. xiv, p. 171.

as a biologic unit; Hoche (1899) had admitted that the histologic unity of the neuron could no longer be upheld, but urged that it was a functional-trophic unit. Münzer (1899) took the stand that the neuron doctrine was better founded than ever, and that the criticisms of Nissl and Bethe were without weight. Auerbach (1899) supported a modified neuron doctrine, while Semi Meyer, von Lenhossék, van Gehuchten, and Ramón y Cajal could see no reason for changing the original conception and doctrines. Max Verworn, in a collective review read before the German Society of Naturalists in 1900 took almost precisely the stand I took in 1899. The two longest publications of the anti-neuronists are those of Bethe (1903) and Nissl (1903). Bethe's book,⁷ while it represents a vigorous attack on the neuron doctrine, embodies the results of most interesting and important original researches, and should be carefully read by every neurologist. Nissl's large volume,⁸ which was reviewed for the *Psychological Bulletin* by Dr. Adolf Meyer, is devoted entirely to controversy and is looked on by ardent neuronists as a sort of attenuated curse of St. Erulphus on the neuron doctrine and its supporters.

In December, 1903, by good fortune, I happened to be in Madrid just at the time when Ramón y Cajal⁹ announced his discovery of a new and easy method for demonstrating the neurofibrils. He kindly showed me his preparations, which made clear at a glance that a flood of new light was at once to be thrown on these remarkable constituents of the nerve cells and nerve fibers (Figs. 6, 7 and 8). His method is simple, is easily applicable to invertebrate as well as to vertebrate tissues and to the embryonic nervous system as well as to that of the adult. It stains the fibrils much more perfectly than is possible with the methods of Bethe and Apáthy, and has the further advantage that it leaves the glia entirely unstained. A somewhat similar, though more complex, method, devised independently and almost simultaneously by Bielschowsky¹⁰ of Berlin, is also now much used for demonstrating the neurofibrils. The finest fibrils are said to be best shown by still a third method, that of the Italian investigator, Donaggio¹¹ (Fig. 9).

Let us now turn to an examination of the principal points which have been under discussion of late and see what is the actual state of knowledge concerning them.

(a) *The Neurofibrils, Golgi Nets and Interneuronal Relations.*—Studies by the methods of Cajal and Bielschowsky and by the method of Donaggio have shown how rich and delicate the network of neurofibrils in the nerve cells is. Bethe's method stained only the coarser strands, which, therefore, looked like isolated fibrils. The newer methods demonstrate finer fibrils, forming anastomoses among these. Bethe's schemata (Figs. 10,

11, 12 and 13) of varying arrangements of neurofibrils as the animal scale is ascended are not confirmed by these newer methods. On the contrary, the nerve cells as regards the neurofibrils are similarly built throughout the whole animal series. There appear to be no independent neurofibrils, but only neurofibril networks embedded in the nerve-cell protoplasm (see figures). The network extends through the whole neuron, but the mass of the network may increase or diminish in size in various parts. Thus there is a large fibril network in the cell body, and this is connected by the attenuated fibril network of the axon, with expansions of the network in the terminal fibers. The so-called "end-feet" of Held are now known to be identical with the terminal buttons of Auerbach, and these, ending on the surface of the cell body and dendrites, are exquisitely demonstrated by Cajal's method (Fig. 14). I have placed a specimen under the microscope illustrating them. These terminal buttons contain neurofibril networks. Nowhere, in specimens stained by Cajal's method or by Donaggio's method, in the cell body or in the terminal buttons, thus far have the neurofibrils been seen actually at the surface; it is stated that there is always an area of fibril-free protoplasm between the networks and the cell boundary.

These recent methods which stain the neurofibrils so exquisitely do not reveal any extraneuronal neurofibrils whatever, either in the region of Nissl's "nervous gray" (Cajal, Retzius) or in the so-called point substance or neuropileum of invertebrates (Cajal, Retzius) (Fig. 15). The whole area of Nissl's nervous gray appears in Cajal's specimens as a feltwork of dendrites and terminals and collaterals of axons containing neurofibrils within their protoplasm. The Golgi nets do not stain at all with Cajal's neurofibril method. Moreover, Held, by other methods, has concluded that they are derivatives of the glia; both he and Donaggio deny their nervous character. There is some evidence that the terminal buttons, to which I have referred, reach the protoplasm of the nerve-cell body by lodging in the meshes of the Golgi net. No one has been able to demonstrate any relation between neurofibrils and Golgi nets. In the light of these newer studies the enormous importance attributed by Bethe and Nissl to the Golgi nets seems, therefore, to have been premature; their views are unsupported by facts.

(To be continued.)

THE BLOOD-CLOT DRESSING IN MASTOIDECTOMY, CONSIDERED PHYSIOLOGICALLY.*

H. O. REIK, M.D.

Associate in Ophthalmology and Otology, Johns Hopkins University, BALTIMORE.

That the special surgeon can profit largely by keeping in close touch with general surgery is generally admitted, but that all surgeons would gain immeasurably from as intimate an alliance with physiology as they have established with anatomy and pathology is a fact, perhaps, not so well recognized. Commenting on this matter, in his last review of surgery, in the December number of *Progressive Medicine*, Dr. Bloodgood alludes to the fact that the physiologist, not specially interested in practical surgical questions and not brought into contact with the daily vital problems confronting the oper-

* Read before the Southern Section of the American Laryngological, Rhinological and Otolological Society at the annual meeting, held in Norfolk, Va., 1906.

ating surgeon, during his scientific investigations, learns many physiologic facts which would be of great value to the surgeon, yet, with the rarest exceptions, this valuable information is lost, so far as the practical surgeon is concerned. An occasional collection and fitting together of bits of knowledge gained in the course of many physiologic investigations, studies made perhaps without a thought of their bearing on surgery, might enable us to elucidate some of the important problems with which the surgeon has to deal. The possibilities of such a plan occurred to me some months ago while listening to a discussion on the treatment of mastoiditis and, being deeply interested in the blood-clot dressing of the mastoid wound, I determined then to consider from the physiologist's point of view the advisability of employing that method.

It is only a few years since aural surgeons were discussing with great animation the proper method of procedure for the opening of the mastoid process when diseased. To-day we do not debate over the propriety of a simple incision in the overlying soft tissues, a small perforation in the outer cortical layer of the bone or the more extensive invasion of the mastoidal cellular structure; unanimity of opinion has been reached on that point. The history of the development of the operation of mastoidectomy has been furnished us in a most interesting and entertaining way by Dr. Whiting, and we will certainly all agree with him without cavil, however we may differ in the details of performing the operation, in the dictum that the operation of the present period has for its prime object the complete and immediate eradication of all the diseased tissue. In other words, in every operation for mastoiditis the surgeon now endeavors to remove every particle of pus, detritus and necrotic or carious bone, even though he be compelled to obliterate the cellular structure of the tip, the zygomatic process and the occipital region, or to invade the cranial cavity itself. Assuming that all this has been accomplished, however, does it constitute a complete operation?

I think we may accept as applicable to mastoid surgery a statement made by J. Collins Warren,¹ with reference to osteomyelitis, that: "Modern surgery demands a complete operation; that is, one which insures rapid and permanent healing of the wound." Permanent healing of the wound will usually follow such an operation as is referred to above, but rapid healing is not so commonly assured. The ideal operation might be described as one which gives the greatest promise of a cure in the shortest possible time and at the least expense of comfort to the patient. If a mastoid wound be dressed with sterile or antiseptic packing at the time of operation, the period of healing will vary from three weeks to several months; very rarely will complete closure occur in less than this time, and I have frequently seen cases that required dressing over a period of six months. It can not be denied, either, that these dressings are often distressingly painful to the patient and always time consuming and more or less annoying for the surgeon. If a method of dressing the wound can be devised which will promote rapidity of healing without additional risk to the welfare of the patient, it will certainly add very materially to the comfort and happiness of both patient and operator. Such a method, I believe, has been provided for us in the blood-clot dressing, first recommended for use in the mastoid

operation by Dr. Clarence J. Blake, of Boston, with whose papers on the subject all of you are doubtless familiar.

The primary object of this dressing is to obtain healing of the wound by first intention, but, when this occurs, other advantages accrue; for instance, the normal contour of the mastoid process is restored, the resulting scar is a mere line which is entirely hidden from view by the auricle, and the period of healing is reduced to five or seven days, with practically no after-treatment. No deformity, almost no scar, and primary union constitute, on the whole, a stake worth playing for. On the other hand, in cases in which the blood clot fails to organize, there is no additional risk to the patient; should the wound not have been so clean as was supposed or should the clot become infected in any one of various possible ways, it simply breaks down and the wound has to be opened, cleansed and packed in the usual way, the patient then being in practically the same position he would have occupied had the open method been employed primarily.

With the modern teachings of surgery constantly before us, that all pus cavities should be treated as open wounds and compelled to fill up by granulation from the bottom, it is not surprising that this suggestion of Dr. Blake should have been received with skepticism. As I have talked with my confrères or listened to the discussion of the subject in otologic congresses, it has seemed to me that men hesitated to employ the method, first, because of a fear of the possible consequences of inclosing in the wound some microscopic particles of infective material and, second, because they considered the normal blood clot a favorable medium for the growth of bacteria. So far the answer to these expressed or implied criticisms has been solely in the nature of relating clinical experiences. A certain percentage of excellent results have been shown by those who have used the blood-clot dressing and as yet no one has related any unpleasant experience.

It is my purpose to take up these objections from another point of view, namely, to consider what happens when a clean cavity in bone tissue is filled with healthy blood clot, what power such a clot may have to overcome infective material that may have been inadvertently left in the wound, and whether general surgeons have any analogous experiences with other portions of the bony frame work, to assist us in drawing conclusions regarding the mastoid portion of the temporal bone.

Experimental and clinical studies have shown that if any clean wound be filled with the patient's own blood, and safeguarded from later infection, the blood clot tends to organize and new tissue, similar to that inclosing the clot, soon forms to replace the latter. The blood flowing into the wound cavity rapidly clots and the fibrous framework of this clot constitutes a scaffolding on which the new tissue is built. Fresh granulations spring from the walls of the cavity and grow out into the clot, forming a new fibrous connective tissue, the nature of which is further altered to accord with the character of the surrounding cavity walls; that is, if the wound be made in bone, osteoblasts are sent out from the bony walls or from the periosteum to convert the fibrous substance into osseous tissue. The migratory power of these osteoblasts is limited, and they travel only a short way from their starting point, so that, in the case of a large cavity in bone, the newly-formed bone does not extend far from the cavity wall, and the

¹ "Surgical Pathology," J. C. Warren, 1895, p. 214.

center of the new-formed tissue remains fibrous in character. It seems quite probable, however, that in a small cavity, such as we ordinarily make in the mastoid process, the osteoblasts, reaching out from all directions, may extend a sufficient distance to meet in the center and thus to complete the construction of a new bony process. Just how early this osteoblastic activity commences is not known, but such cells have been observed to form within forty-eight hours after the operation, and it is certain that granulation tissue grows more rapidly into a healthy blood clot than into space. It is plain, then, that Nature may be greatly aided in the reconstruction of destroyed tissue by providing an excellent framework on which to build and leaving her only the task of furnishing vascularity and new tissue cells.

But, suppose the wound cavity to be treated is not absolutely clean, that some invisible particle of septic material is present when the blood is introduced, has the blood any bactericidal or antitoxic powers? A long series of observations by the most careful investigators has clearly proved that the normal human blood does possess such properties. Metschnikoff, Nuttall, Fodor, Lubarsch, Vaughan and Novy and a host of others have published most interesting work on this subject. From their several experiences we may safely draw the following conclusions: The normal human blood possesses bactericidal power, varying in degree in its antagonism to different micro-organisms; this property of the blood is greater after it is drawn from the vessels than while circulating intravascularly; the microbe-destroying substance is found in the serum, but is produced by the leucocytes; certain chemical changes in the blood may be induced either to increase or to diminish its bactericidal power, and this property of the blood naturally diminishes after the clot is forty-eight hours old.

Nuttall, following a suggestion of Metschnikoff, was probably the first to demonstrate the bactericidal power of normal blood serum. Working under the direction of Flügge, in 1888, he used defibrinated blood taken from various species of animals and found that this blood destroyed the *Bacillus anthracis*, *Bacillus subtilis* and the *Staphylococcus pyogenes aureus* when brought into contact with them. He also confirmed the finding of Fodor that after awhile the blood loses its germicidal properties and becomes a suitable culture medium in which germs grow abundantly.

The fact having thus been determined that the blood serum removed from the body acts far more rapidly and energetically on microbes than the plasma and lymph within the body, the disparity of action was further shown by Lubarsch,² who attempted to ascertain the exact power of the blood of some animal over a given serum; using the bacillus of anthrax and experimenting on rabbits, he injected known quantities into the circulating blood and found that this animal was quite able to take care of a dose of less than 16,000 germs, but if a larger number were injected fatal infection resulted. If he drew a small quantity of blood from an animal of the same class and size into a test tube and inoculated that with the same micro-organism, many times that number of germs were destroyed; that is, one cubic centimeter only of the rabbit's blood serum would destroy more than 16,000 of these germs when inoculated into the clot outside the body, and he could not, after a few minutes, reproduce them by culture from the clot.

Then a most interesting series of investigations followed to determine what element of the blood possessed this bactericidal quality and how it acted. Vaughan and McClintock have presented the most conclusive report on these points, and they hold that the leucocytes secrete some substance which is poured into the serum, that this substance is a proteid, and that the only proteid likely to be present in blood serum to which such properties could be attributed is nuclein.

The clotted blood possesses greater power than the circulating blood probably because in the formation of the clot the leucocytes break down and discharge their entire complement of this nuclein. Other workers have demonstrated the transient duration of this power in the blood clot, a power which seems to diminish rapidly after forty-eight hours, and the fact that certain chemical changes in the clot may cause a variation of its power. The bactericidal power seems to be present in freshly drawn blood only when it is alkaline in reaction. If its alkalinity be raised above normal the bactericidal power will be somewhat enhanced, but if the blood be below normal alkalinity or if it be rendered acid in reaction such power is diminished or actually destroyed. The nuclein acts only in an alkaline serum. Again, if alcohol be added to the blood, the bactericidal property is destroyed through the precipitation of the albuminoid constituent. Bichlorid of mercury, likewise, has a deleterious influence on the bactericidal property of blood serum.

These chemical experiments have an important bearing on the use of blood clot as a surgical dressing.

The use of carbolic acid and alcohol for the cleansing of the wound, as an extra precaution of cleanliness, prior to the introduction of the blood, has been recommended by some surgeons, but it seems not unreasonable to venture the suggestion that some of the failures with the blood-clot dressing may have been due to excessive zeal in the use of carbolic acid and alcohol for antiseptic purposes. If exact neutralization were possible and the wound left in a neutral state, no harm could result from the employment of these substances, but if there be left any measurable quantity of either it militates against success. On theoretical grounds it would appear more rational to rely on dry cleansing of the wound with instruments and sterile sponges, or to wash the cavity with sterile salt solution which, if it produces any effect on the coming clot, renders it more alkaline and increases its power to control septic material.

Leaving the realm of experimental medicine and turning to practical surgery, we find, again, the strongest possible indorsement for the employment of healthy blood clot in the healing of wounds. Most physicians are familiar with the epoch-making report of Schede, "Ueber die Heilung von Wunden unter dem feuchten Blutscharf," or know of the most excellent results obtained by Halsted and his associates in the treatment of osteomyelitis by this method. The whole subject was excellently presented by Professor Halsted several years ago and, as there is no higher authority, I could do no better than quote from his paper.³

After reviewing the objections to leaving blood in wounds and the bearing of Lister's work on the subject, he says:

"Although perfectly familiar with the organization of the

2. Albutt's System of Medicine, vol. I, p. 89.

3. Johns Hopkins Hosp. Reports, vol. II, p. 255-261.

blood clot, it apparently never occurred to Lister to make a systematic effort to utilize the blood clot and to imitate Nature's method of disposing of the dead spaces in wounds.

He has taught us what can be done under the cover of antiseptics. One may maltreat the tissues to any extent, mutilate the wound during the operation in every possible way, cut off by ligatures the circulation in large masses of tissue, produce extensive areas of superficial necrosis by irrigation with antiseptic solutions, stuff the wound with gauze and drainage tubes, tear out the stuffing and with it the granulations which have grown into it, restuff, etc., and still the wound may heal without suppuration, without septic inflammation and in a way which is, perhaps, altogether satisfactory to the surgeon.

But now that wound infection is for many surgeons almost a thing of the past, we may ask ourselves if, after all, our wounds are ideal wounds. One naturally hesitates to attempt to give one's notion of an ideal wound. This ideal wound of to-day may not be his ideal wound of next year or even of tomorrow. I conceive an ideal wound to be one which immediately after the operation is reduced to the condition of a non-penetrating subcutaneous wound, and which is as free as this is from the dangers of infection.

Impressed by the work of Küster, Neuber and others, and entertaining with them the same fears of blood in wounds, it was my practice for several years to attempt with the utmost care to obliterate the dead spaces in wounds. The results were gratifying, but the technic was often very tedious. For example, after an amputation of the thigh it would not infrequently take an hour to obliterate all the dead space. The mechanical problems were sometimes quite difficult, and one was perpetually annoyed by the fear that he might strangle the tissues included in the sutures. After a time I became convinced that it was impossible to obliterate thoroughly all the dead spaces in some wounds, and I observed that wounds in which the dead spaces were not obliterated healed throughout by first intention just as regularly as did the other wounds. I was, therefore, quite prepared to welcome Schede's article on the healing of wounds under the moist blood scab. This contribution by Schede I believe to be the greatest which has been made to the technic of surgery since the introduction of antiseptic methods by Lister.

The immortal John Hunter was many years in advance of his time when he expressed himself on scabbing and the organization of the blood clot as follows: "In many deep-seated wounds, where all the parts have remained in contact, those unnerneath will unite much better if the surface be allowed to scab. Some compound fractures (more especially where the external wound is very small) should be allowed to heal in the same way, for by permitting the blood to scab on the wound, either by itself or when soaked in lint, the parts underneath will unite, the blood under the scab will become vascular and the union will be complete even when the parts are not in contact. Many wounds ought to be allowed to scab in which this process is now prevented, and this arises, I believe, from the conceit of surgeons who think themselves possessed of powers superior to Nature, and, therefore, have introduced the practice of making sores of all wounds."

From these and similar experiments and experiences, I think we are fully justified in using the blood-clot dressing to complete the operation of mastoidectomy, and I only wish to add a few words regarding the technic of its employment. You will infer from what I have said that very little can be done to assist the blood clot in its possible conflict with overlooked septic material, but a good service can be rendered by avoiding some things that would tend to hinder the blood in its beneficial work.

In the first place, the nearest possible approach to absolute surgical cleanliness must obtain throughout the operation. This applies not only to the operator and

his assistants, to the sterilization of all instruments and the protection of the operation field by proper sterile sheets or towels, but also the perfect removal, so far as can be determined, of every particle of infective material and of diseased tissue.

Next, it is exceedingly important that the wound be closed in such a way as to prevent the introduction of new infection and to promote primary union. It is my opinion that a good many failures with the blood-clot dressing have been the result of faulty closure of the soft parts. Shreds of tissue that may be infected or that would prevent neat apposition of the margins should be cut off. Chemical sterilization of the wound should not be attempted. If irrigation is considered necessary, sterile normal salt solution may be employed. Finally, for the closing of the wound, the subcutaneous silver wire suture recommended by Halsted may be used.

All physicians are familiar with the experimental work performed some years ago by Professor Welch on the sterilization of the skin. Making use of the most approved methods of cleansing the skin's surface, he could still secure a bacterial growth from the deeper layers of the corium and he determined that this region was the natural habitat of the *Staphylococcus epidermidis albus*, which germ was the active factor in the production of the common stitch abscess. If the sutures be carried through the skin from side to side of the wound, it not only makes the opportunity for a stitch abscess, but opens up a new avenue for infection of the clot. In many instances this will not be sufficient to cause a breaking down of the clot, but if that blood is having a battle with septic particles within the cavity this may be the last straw needed to cause a breakdown.

Furthermore, in the subcutaneous method of suturing wounds, silver wire is the best material to use because it possesses antiseptic properties of its own. Some years ago Bolton, working in Kelly's laboratory, undertook to ascertain the relative value of suture materials, and he found that the best of all was copper wire and next to this came silver; inasmuch as the latter is, for commercial reasons, most available and the antiseptic properties but slightly different, he recommended the general use of silver. It can be easily and surely sterilized by boiling, while catgut is, under the best of circumstances, unreliable and silk is only less so. With a subcutaneous silver wire thread, lacing the wound from side to side, and not penetrating the skin at any point, one has a suture easy of introduction, perfectly sterilizable, strong enough to bear any traction necessary to secure good apposition of the wound lips, and removable without pain at the proper time. A layer of silver foil over the closed wound, before the sterile gauze dressings are applied, will add something to the protection against septic invasion.

It may be too much to say that the complete operation referred to here and described so well to-day by Drs. McKernon and Bryant, with the blood-clot dressing, will constitute the ideal, but I believe it will come to be accepted as the standard operation of mastoidectomy.

Stokes-Adams Disease in Incipient Paresis.—M. E. Rist (Bull. et. Mem. de la Société Méd. des Hôpitaux) reports a case of Stokes-Adams disease complicating the early stages of paretic dementia of syphilitic antecedents. The relation between the bradycardia and the meningo-encephalitis seemed evident, but he remarks that, while lues is known as a cause of either condition, the combination here seems novel.

SOME OBSERVATIONS ON CEREBRAL PARALYSIS.*

DANIEL R. BROWER, M.D., LL.D.

Professor of Nervous and Mental Diseases, Rush Medical College, CHICAGO.

These observations will be limited to the cases of paralysis that are the result of cerebral embolism, hemorrhage or thrombosis.

These three pathologic conditions constitute the vast majority of the cases. The records of Cook County Hospital for 1903 show four cases of embolism, sixty-five cases of hemorrhage and twenty cases of thrombosis. In thirty-two cases of cerebral paralysis the pathogenesis was in doubt. The records of the year 1904 show six cases of embolism, sixty-nine cases of hemorrhage, thirty-one cases of thrombosis and thirty-four cases in which the pathogenesis was doubtful.

Differentiation was made either in the postmortem room or by a medical staff very skilled in diagnosis, and they differ somewhat from the ordinary published records of such cases. They show an immense preponderance of hemorrhage, and this should be remembered at the bedside when an effort is being made to work out a diagnosis in any given case.

The records of the health office of Chicago give the following interesting results:

DEATHS—Total from apoplexy, first period, 1885-1904	4,652
Second period, 1895-1901	6,036
Actual increase, second period	1,383
POPULATION—Average yearly, first period	287,444
Second period	1,675,690
DEATH RATES—Apoplexy, per 10,000 of population, first period	4.7
Second period	3.6
Per cent. decrease, second period	23.4
RATIO—Apoplexy deaths to total from all causes, first period	2.5
Second period	2.4
Per cent. increase, second period	4.3

The percentage of decrease in the second period as set forth by the table is interesting. The death rate of Chicago has been decreasing for several years, until today it shows a record that is very remarkable, being the lowest of any large city in the world. This decrease in cerebral apoplexy, which corresponds with a decrease in nervous diseases generally during the second period, is an encouraging outlook and would seem to show that the people of that strenuous city are adjusting themselves physically to the conditions there.

ETIOLOGY.

Cerebral paralysis in the cases to which these observations are limited is the result of periarteritis or endarteritis, producing hemorrhage or thrombosis, and endocarditis resulting in embolism.

The periarteritis or endarteritis in the case of hemorrhage weakens the muscular coat of the vessel and produces aneurisms, usually military, and the process continues until the walls become so feeble that rupture occurs. In the case of thrombosis the intima becomes roughened and gradually fibrinous deposits take place, little by little obliterating the lumen until finally occlusion occurs. In the first case the blood vessel carries the blood current with sufficient success to meet the ordinary demands of the brain for nutrition until the moment that rupture occurs. Hence there is in hemorrhage usually an absence of prodromal symptoms. In the second case the process of obliteration is slowly carried on and the nutrition of the brain is more or less interfered with from the beginning; therefore, prodromal symptoms are the rule, such as headache, vertigo,

transitory paresis and aphasia and a sense of general discomfort in cerebral function.

In the case of endocarditis there is as a sequence the formation of polypoid vegetations on the valves of the heart, and later these vegetations become detached and are carried by the blood current until they reach a point beyond which they can not pass and occlusion occurs. For anatomic reasons with which you are perfectly familiar, the usual route traveled by an embolus is the left common carotid artery, the left internal carotid, the left middle cerebral, and the occlusion occurs in one of the branches of this artery that supplies the basal ganglia and the internal capsule. There is under these circumstances no interference with the brain nutrition until the very moment occlusion occurs, and, therefore, there are usually no prodromal symptoms, except such as are of a general character that may arise from an uncompensated heart.

The cerebral circulation is remarkable in the comparative absence of anastomosing branches, in the terminal character of the vessels, and in the fact that they lie in the perivascular spaces without the usual protection that contiguous tissue gives in other parts of the body, and the seriousness of any one of these pathologic processes is greatly increased by the interference that it produces in the brain with the lymph circulation. The vessels that supply the basal ganglia and the internal capsule, arising directly from the middle cerebral arteries, are comparatively large and have generally a high blood pressure, and the pathologic process that occurs here is not only more extensive, but more frequent.

In these several pathologic conditions we must not only consider the direct damage done to the brain by the destruction of neuraxons that lie in the focus of the lesions, but around about this focus there is always an area more or less extensive of collateral edema and exudation that for a time effectually destroys the functions of the territory.

The apoplectic coma must be differentiated from the syncope of alcoholic intoxication, from the coma of epilepsy, uremia, diabetes and from drug poisoning. In some cases this is extremely difficult. An eminent medical practitioner of Chicago some few years ago left his home to visit a case some distance away. He was quite fatigued on leaving his home and took a drink of whisky. Before he reached the house of his patient he fell on the sidewalk; a policeman, passing by, recognized him, smelt the alcohol on his breath, jumped to the conclusion that the doctor was intoxicated, carried him to a near-by drug store, and placed him in a rear room until he would recover from the alcoholic intoxication, as he supposed. A doctor, who officed over the drug store, was called in to see him, and he accepted the diagnosis of the policeman. When morning came the good doctor's coma, if anything, had deepened, and then consultation was called and his family notified. At the time of consultation there was but little difficulty in the differentiation. The muscular tonus of the two sides was different; there was conjugate deviation of the face and of the eyes. Skin reflexes were lost on the paralyzed side. There was a well-defined Babinski toe sign. Arterial tension high. Rectal temperature lowered. Temperature on the paralyzed side increased. Perspiration marked on the paralyzed side. These several symptoms and the absence in the history of prodromes rendered the diagnosis of cerebral hemorrhage possible, which was subsequently verified by postmortem. Mistakes

* Read before the Sioux Valley Medical Association.

such as were made in this case are not at all infrequent in large cities and warn us that we should always be on our guard and not be led astray by alcoholic odor on the breath. I regard the conjugate deviation of the face and eyes and the Babinski toe sign when present (unfortunately they are not always present) as invaluable pathognomonic signs.

In thrombosis we should expect a series of prodromal symptoms covering a space of several months, a low arterial tension, a slight degree of coma, unchanged temperature, and a pale face. In a recent case of cerebral paralysis, however, prodromal symptoms that were present for a few days before the apoplectic seizure and the normal arterial tension resulted in a diagnosis of cerebral thrombosis, when the postmortem findings gave cerebral hemorrhage.

I am very much of the opinion that we should be extremely guarded in reaching positive conclusions as to whether a given case is one of hemorrhage, thrombosis or embolism. In embolism we do not expect arteritis, we do not expect prodromata, and we do find valvular heart disease, but we must bear in mind that a valvular heart disease is not inconsistent with the possibilities of either thrombosis or hemorrhage.

The prognosis in cerebral paralysis is grave in proportion to the depth and duration of the coma. Cheyne-Stokes respiration will always make the prognosis serious, and convulsions add greatly to the gravity. Acute bed-sores are also serious indications. Sudden elevation of temperature will make prognosis doubtful, and an attack, no matter how slight, implies probability of a recurrence. In favorable cases improvement will be manifest at the end of a week. Early contractures are not serious in their import, but contractures that occur about a month after the seizure are an evidence of a descending degeneration in the motor tract, and this usually means that no further improvement can be expected.

TREATMENT.

The preventive treatment of cerebral hemorrhage or thrombosis is the treatment of the arterial degeneration on which they both depend. The etiology of this is sometimes clear enough, and when it can be determined the treatment will suggest itself. I think the specific relations to arterial degeneration are sometimes overlooked. I am of the opinion that degenerations of arteries that are found in younger people, in the absence of interstitial nephritis, of very pronounced chronic alcoholism and tuberculosis, are specific and demand the use of mixed treatment to the maximum capacity of the individual. Those cases that do not have a specific history are much benefited by a course of chlorid of gold and sodium. This drug should be rubbed up dry with the pulverized resin of guaiac, put dry in a capsule, and administered before meals. Along with this there must be a proper attention to elimination by the skin, kidneys and bowels and due attention to the digestive function.

The treatment of the apoplexy depends on the diagnosis of the lesion. If you are sure that it is hemorrhage, reduce arterial tension, administer erlen oil, thereby bleed the patient into his own abdominal vessels. Apply ice to the head; hot mustard plaster to the feet. If possible, tincture of aconite, frequently repeated, in full doses. Have the head of the bed raised. If you are sure the lesion is thrombosis, the treatment should be diametrically opposite. Increase arterial tension by strychnia and other cardiac tonics; avoid active

purgation. In the great majority of cases the safe treatment will be characterized by a masterful inactivity. Quiet, warmth, cleanliness, position in bed to secure the best respiratory activity, due attention to the bladder and bowels are safe indications in every case.

With the disappearance of the apoplexy, attention should be given to the paralyzed muscles. Gentle massage and passive movements that will preserve the nutrition of the muscles are indicated from the beginning. The muscles in cerebral paralysis atrophy with rapidity sometimes; especially is this the case with the deltoid, and if the muscles are not maintained in a proper state of nutrition when the collateral edema already mentioned disappears function can not be re-established. In my experience, this very important consideration is often overlooked. After about ten days mild faradic exercise of the muscles should be commenced and used every day. The sances should be short, remembering that it is easy to produce exhaustion in the muscles, thereby defeating the object of the treatment. Two or at most three contractions of each muscle or group of muscles at each sance is enough, and the least current that will produce this result should be used.

There is a difference of opinion as to the value of cerebral galvanization in these cases. For my own part, I am confident that a mild constant current of from two to five milliamperes, positive electrode to the head and negative to the nucha, for about five minutes daily, favors the disappearance of the edema and exudations and the retrograde changes that must take place in the pathologic focus. I, therefore, advise cerebral galvanization.

As soon as there is any appearance of returning voluntary power the patient should be encouraged to exercise it freely, and many failures in treatment result from a want of persistent effort in this direction. The moderate use of the iodids and of the easily assimilable preparations of phosphorus assist in bringing about the necessary nutritional changes in the brain and in maintaining the general health of the patient while the process of repair is going on.

Aphasia, a common symptom in right hemiplegias in right-handed persons, can often be greatly benefited by education. A few years ago a young man received a gunshot of the head, resulting in right hemiplegia and aphasia. Little by little the hemiplegia disappeared; the aphasia remained. His sister, under my instruction, began the work of re-educating him. I presumed the speech center on the left side of the brain was destroyed, and I think the excellent work she did after twelve months resulted in his being able to talk with very great facility was a consequence of an education of the center on the other side—the center of left-handed persons. But be it as it may, the result was a restoration of his speech capacity, and what was done in his case can be done in other cases by an earnest and persistent effort. I have almost succeeded recently in accomplishing the same result in a much older person after several months' earnest work by a wife and daughter. In this case there was a reacquisition not only of the speech capacity, but of the writing capacity, and when the person writes slowly he writes well; when he talks slowly and deliberately he articulates well.

I think we are very much disposed to neglect this educational feature in the treatment of cerebral paralysis.

34 Washington Street.

DOUBLING OF THE CARDIAC RHYTHM AND ITS RELATION TO PAROXYSMAL TACHYCARDIA.

ALBION WAITER HEWLETT,

Instructor in Clinical Medicine at Cooper Medical College.
SAN FRANCISCO, CAL.

Paroxysmal tachycardia derives its name from the characteristic paroxysms of extremely rapid heart action that occur from time to time. These usually begin abruptly, last for minutes, days or weeks, and finally end almost as abruptly as they began. During the paroxysm the pulse rate ordinarily ranges between 180 and 300 a minute. At times the patient is hardly conscious of his condition. More frequently, however, he suffers from various cardiac symptoms, such as palpitation, dyspnea and painful or oppressive sensations in the precordium. In severe cases, well-marked signs of cardiac insufficiency, such as venous stasis and edema, may be present.

No adequate physiologic explanation of this form of tachycardia has been given. In many of its features it suggests a neurosis, yet attempts to produce a similar acceleration experimentally, either by stimulation of the accelerator or by division of the inhibitory nerves to the heart, have failed. Recent observations have thrown quite a new light on the nature of paroxysmal tachycardia and these new facts must hereafter find a place in any attempt at an explanation of this most remarkable affection. It has been demonstrated that, in a number of patients at least, there is an abrupt doubling of the heart rate at the beginning of the paroxysm of tachycardia, and that the return to the original rate is sometimes as abrupt as the onset.¹

Considerable interest, therefore, is attached to the phenomenon of a doubling of the cardiac rhythm. The following case is reported partly because it adds another to an already interesting series of cases and partly because it serves to prove that a doubling of the pulse rate may occur, even though none of the clinical features of paroxysmal tachycardia are present. For permission to report this case I am indebted to Dr. J. O. Hirschfelder, in whose wards these observations were made.

Patient.—T. C., a longshoreman, aged 59, was admitted to the City and County Hospital of San Francisco, Sept. 27, 1905, his complaint being shortness of breath.

History.—His family history was negative. He had been a very healthy man up to the present illness; he denied venereal infection. He drinks regularly five or six whiskies and five or more glasses of beer daily. He chews and smokes to excess and is accustomed to very heavy labor.

Present illness.—The patient felt well till seven months ago, at which time he first noticed some shortness of breath on exertion. This dyspnea gradually grew worse until finally it became continuous and so bad that he was compelled to assume the sitting posture at night in order to sleep. He has had some edema of the feet and legs. About one month ago his left pleural cavity was tapped and a large quantity of fluid withdrawn. He has an occasional cough, with slight yellowish expectoration. At times he has pains in the left side of his chest, made worse by coughing. For the past three weeks he has been passing unusually large quantities of urine, and his edema has practically disappeared. Occasionally he has slight headaches; there are no other serious symptoms.

Examination.—The patient is a well-developed but somewhat

emaciated laboring man. Conjunctivæ are pale. Lips and fingernails are pale and cyanotic. Pupils are normal. There is a slight arcus senilis. Tongue and throat are negative. The chest is somewhat barrel-shaped. The lower right side moves somewhat better than the left. In the right interscapular region there is slight dullness, with increased fremitus and harsh expiration, but it is doubtful if these represent any more than the normal difference between the two sides. No râles could be heard.

Heart.—A diffuse pulsation is visible over the precordium, with the point of maximum impulse in the fourth intercostal space 8 cm. from the median line. There is a heaving impulse on palpation. The area of cardiac dullness begins above at the middle of the third rib and extends 8 cm. to the left of the median line and 3 cm. to the right. At the point of maximum impulse the first sound is well heard and clear; the second sound is faint and it is accompanied and followed by a faint blowing murmur. This diastolic murmur is heard over the whole of the precordium, being loudest in the third and fourth intercostal spaces near the sternum and very faint over the aortic area. During his stay in the hospital this murmur disappeared. Both second sounds are faint. The radial arteries are much thickened and slightly nodular. There was no collapsing character to the pulse even at a time when the diastolic murmur was well heard. There was no visible venous pulsation in the neck.

Abdomen.—The hepatic flatness begins at the upper border of the sixth rib and extends to the costal margin, the total vertical flatness being 10.5 cm. in the mammary line. The edge of liver could not be felt. Splenic dullness was not enlarged and the spleen could not be felt. The kidneys were not palpable. Pulsation of the abdominal aorta could easily be felt. Reflexes were normal.

Urine.—Specific gravity, 1.010; clear, neutral, amber, no albumin, no sugar; microscopically, a few hyaline and finely granular casts were seen.

The history of the patient was that of a man who had suffered from a gradually progressing and rather serious cardiac breakdown, with urgent dyspnea, general anasarca, and a left hydrothorax. At the time of admission he had partially recovered from this breakdown, and during his stay in the hospital he continued to improve until at the end of two months he was able to leave and to do light work. It is difficult to define the exact nature of his cardiac lesion. The faint diastolic murmur heard at the first examination was probably of but little importance, for had it denoted an aortic lesion of any severity the pulse would probably have shown a collapsing quality and the murmur would not have disappeared during his stay in the hospital. This murmur is probably to be classed among the functional diastolic murmurs, the most frequent of which are transmitted venous murmurs.² We have no reason to suspect a neurosis in this patient, for with a high grade of cardiac insufficiency he presented absolutely no neurotic stigmata and no abnormal cardiac sensations. By exclusion, therefore, we are led to diagnose a lesion of the heart muscle, which diagnosis is strengthened by the history of such etiologic factors as hard work, the abuse of alcohol and tobacco, and marked peripheral arteriosclerosis. No history of typical attacks of paroxysmal tachycardia could be obtained. The history was rather that of a gradually progressing cardiac breakdown followed by an equally gradual recovery. At no time did the pulse rate rise above 145 a minute.

During the examination of September 29 it was noticed that the heart rate as observed at the apex changed abruptly, according to the position of the patient, without his being in any way conscious of such a change.

2. Cabot and Locke: *Johns Hopkins Hospital Bulletin*, May, 1903.

While lying flat on his back, the rate varied between 68 and 72 a minute, whereas when he sat up in bed it varied between 134 and 142. The ratio between the two was, therefore, approximately 1:2. Usually the pulse rate as felt at the wrist corresponded to the apex rate. Yet this was not always the case. At times, when the patient was sitting up, only half as many pulsations were palpable at the wrist as at the apex, for the reason that every other contraction of the heart failed to produce a palpable radial pulse. At such times palpation of the apex, as well as tracings taken from this region, revealed no difference either in time or character between the apex beats giving rise to radial pulsations and those failing to do so. By auscultation over the heart, however, it could be demonstrated that the second sounds were barely audible after those beats that produced no palpable radial pulses.

Having found that the heart rhythm altered with change of position, it remained to demonstrate this alteration by graphical methods. Unfortunately, a complete set of tracings were not made on this day; and, although the patient was under constant observation for two months subsequently, the same condition did not recur. Usually his pulse was absolutely regular, its rate varying between 60 and 90 a minute. At times, however, it became very irregular, partly owing to the occurrence of extra systoles and partly owing apparently to an irregular rate of stimulation. Two good tracings, illustrating the change from the fast to the slow rhythm were obtained, both of them being practically identical. Figure 1 shows on the left the rapid rate, the average duration of beats being 2.26 fifths of a second (average taken of 26 beats). It shows on the right the slow rate with an average duration 4.46 fifths of a second per beat (average of 11 beats). The ratio between the two is almost precisely 1:2; in other words, the heart is beating twice as fast in the one as in the other. On the second tracing, not reproduced, the average duration of the short beats is 2.1 fifths of a second and of the long beats 4.1 fifths of a second. Here, again, the ratio is almost precisely 1:2. The normal pulse rate of this patient in bed, as shown by subsequent observations over a period of two months, lay between 60 and 90 a minute, i. e., the average duration of the pulse was 4.2 fifths of a second. We may assume, therefore, that the slower of the above rates represents the normal rate, and that the more rapid rate is caused by a doubling of the heart rhythm.

What physiologic explanation can be given for such a doubling of the pulse rate? According to Englemann, the activity of the heart may be affected in the following four ways: (1) The rate of stimulation may change; (2) the irritability of the heart muscle, its responsiveness to stimuli, may be altered; (3) the conduction of the stimuli from the mouths of the great veins to the apex of the heart may be affected, and (4) the contractile power of the muscle itself may be altered. How can a doubling of the cardiac rhythm be explained in accordance with this hypothesis of Englemann? At first thought one would be inclined to attribute the change in heart rate to an alteration in the rate of stimulation. A more exact analysis of these curves, as well as of those of other authors, fails, however, to support this supposition. In that case, we should expect no such sudden alteration of the pulse rate as is here present, but rather a gradually increasing rate, e. g., from 70 to 80, 90, etc., up to 110 and *vice versa*. A gradual

transition of this character is observed after section of the vagi or after stimulation of the accelerator nerves. It occurs during exercise, excitement, etc. In all of these cases the more rapid heart rhythm is due to an increased rate of stimulation. In the class of cases under consideration no such gradual transition takes place. There is a sudden jump from the slow to the fast rhythm and the return from the fast to the slow is often equally abrupt, as it was in the present case. The only satisfactory explanation hitherto advanced for such an abrupt jump is that put forward by Hoffmann.¹ He assumes that in these patients, and possibly in normal persons as well, the heart is stimulated much more frequently than a study of its rate would seem to indicate, but that it does not contract with every stimulus. In the above patient, for example, we may assume that the heart constantly receives 140 stimuli each minute, but that in the recumbent position it responds only to every other stimulus and that consequently it beats at the rate of 70 a minute. When the patient sits up, the heart then responds to every stimulus and its rhythm changes abruptly from 70 to 140 a minute.

This failure of the heart to respond to every stimulus may be accounted for in three ways according to the Englemann hypothesis: (1) The irritability of the heart muscle, always lessened after a contraction, may not recover after one stimulus in time to respond to the next. The heart would then contract only with every other stimulus. (2) The contractile power of the heart muscle may be similarly slow in recovering with a similar halving of the heart rate. (3) Each stimulus may cause a contraction of the fibers about the mouths of the great veins, but this contraction may not be conducted to the remainder of the heart; in other words, there is a "blocking" of every other contraction wave high up in the auricle. It is difficult to decide in which of these ways the heart fails to respond to every stimulus.

The last or "block" theory derives considerable support from the fact that we may get a second doubling of the heart rhythm. Hoffmann, for example, has observed a pulse rate changing from 60 to 120 a minute and afterward from 120 to 240. If we assume that this heart normally receives 240 stimuli a minute and that its responsiveness to these stimuli gradually lessens, then we should expect that at first it would respond only to every other stimulus and that its rate would become 120 a minute. If, then, its irritability or its contractility were still further diminished, we should expect that it would respond to every third stimulus and that its rate consequently would become 80 a minute. Such a reduction may, indeed, occur, as happened in my own case (Fig. 2), but it appears to be rather exceptional and never of long duration. As a matter of fact, the rhythm drops from 120 to 60, instead of from 120 to 80. It is difficult, therefore, to explain a fourfolding of the rhythm on the theory that the heart muscle is lacking either in irritability or contractility.

The hypothesis of a "blocked" impulse will, however, explain this fourfolding of the rhythm in a very satisfactory manner. We need only assume that the impulse is blocked at two separate points, the one being situated below the other. At the first point every other beat is blocked and the rate is reduced from 240 to 120; at the second point every other beat that remains is again blocked and the rate is then reduced from 120 to 60 per

minute. Kries³ has shown experimentally that a blocking of the cardiac wave of contraction between the auricle and the ventricle of a frog's heart, produced by artificial cooling, follows this same rule, the ratio between the auricular and the ventricular rhythms becoming 2:1, 4:1, 8:1, whereas the intermediate ratios such as 3:1, 5:1 are not obtained. Erlanger,⁴ on the other hand, has shown for the mammalian heart that the 3:1 ratio may be produced experimentally, thereby proving that the 3:1 ratio is not inconsistent with a blocking. In view of these facts, therefore, it would seem that our best explanation of a doubling with subsequent four-folding of the cardiac rhythm is that the heart is receiving a great number of stimuli, but that these are blocked at two successive points, one below the other.

In Figure 1 the rapid beats before the transition show a distinct tendency to vary regularly in size, smaller beats (b, d, f, h, j, l) alternating with larger ones

Fig. 1.—A radial tracing showing the transition from the slow to the fast rhythm. Time is marked in fifths of a second. At * the interne who was listening to the

(a, c, e, g, i, k, m). This phenomenon has been demonstrated far more conclusively by Hoffmann and by Lommel. They observed a diminution in the size of alternate beats which progressed gradually until finally the smaller pulsations disappeared and a half rhythm was established. The transition from the slow to the fast rhythm may take an opposite course, i. e., small beats appear between the larger ones and gradually increase in size until all become equal and the rhythm is doubled. Such observations favor the second of the above explanations of the doubled rhythm, namely that the contractile power of the heart muscle is at fault.

Fig. 2.—A long beat (z) interposed in the slow rhythm. Notice that its length, 6.5 fifths of a second, is one and a half times that of the other beats.

If this power to contract is not recovered quickly enough after a previous contraction, then every other beat may be omitted and the rhythm halved. As the power to contract gradually returns, we get beats of increasing size. So far as Figure 1 is concerned, it will be noticed that the first beat to disappear entirely would have belonged to the series of larger pulsations (it being the second beyond "m"). From this it would appear that the smaller beats are not necessarily the ones that disap-

pear. In another tracing, showing a transition from the fast to the slow rhythm, an alternation in the size of the beats can also be made out just prior to the transition, but in this instance the smaller beats ultimately disappear. In neither case is there a gradual dying out of the smaller beats, as has been figured by Hoffmann and by Lommel. An alternation of small with large beats may even persist throughout the tachycardial attack, and I am inclined to offer this as an explanation of the fact that at times my patient's pulse seemed to be beating only half as fast as his heart. It is quite possible that the alternating small beat was not palpable at the wrist. Unfortunately, no tracings were taken at such a time.

Figure 2, a pulse tracing taken during the slow rhythm, shows one unusually long beat "z" interposed in what would otherwise be an absolutely regular rhythm. The length of this beat, 6.5 fifths of a second, is almost

exactly one and a half times as long as the beats that precede and follow it (4.4 fifths of a second). Precisely similar lengthened beats, five in all, were discovered scattered through a number of other tracings. In all of these the lengthened beat was just half again as long as the ordinary slow beats about it. The cause of this peculiar relation between the length of these beats becomes clear if we recall the hypothesis advanced to explain the doubling of the heart rate. According to this hypothesis, the slow rate results from a failure of the heart to respond to every stimulus received. If now occasionally, instead of failing to respond to every other stimulus, it

failed to respond to two in succession, then the length of the resulting long beat would be three times the length of the stimuli and one and a half times the length of those beats that represent two stimuli. These longer beats, therefore, lend strong confirmation to the hypothesis that this heart received a double number of stimuli during its slow rhythm.

In Figure 1 it will be noticed that the first of the longer beats (n) has a duration of 3.9 fifths of a second, whereas the following beats average 4.46 fifths of a second. I am inclined to attribute this shortening, not to any change in the rate of stimulation, but to a difference in the rate of propagation from the auricles to the

4. "Vorläufige Mittheilung über die Physiologie des Herzblocks in Säugethieren," Zentrabl. f. Physiol., vol. xiv, No. 1.

periphery. Hering⁵ has shown that, in general, longer waves travel to the periphery more rapidly than do shorter waves. This difference in propagation may possibly take place either within the heart itself or in the peripheral arteries. At any rate it is sufficient to explain the shortening of "n."

The question naturally arises as to whether or not we should consider the acceleration in this patient's pulse as an attack of paroxysmal tachycardia. Unfortunately, it is impossible to answer this question with any degree of certainty. If we regard an extremely rapid heart action as a cardinal symptom of paroxysmal tachycardia, then our patient could not be placed in this class, for even in the attack his pulse did not exceed 145 beats a minute. It is difficult to maintain such arbitrary clinical standards, and we all know how greatly the mild forms of a disease may differ from the severe ones. In view of this difficulty, it seems justifiable, at least for the present, to pay more attention to the physiologic peculiarity, the doubling of the heart rhythm. So far as I know, no typical clinical instances of paroxysmal tachycardia have been reported in which such a doubling of the heart rate was proved to be absent. Furthermore, in one of Hoffmann's cases, the doubling of the pulse from 60 to 120 was followed by a second doubling to 240. Had this second doubling been omitted, one might have questioned the nature of the case; yet with the second doubling it became a typical paroxysmal tachycardia.

Whether paroxysmal tachycardia is to be regarded as a definite disease or whether it is merely a symptom-complex must remain undecided. The pathologic anatomy of the condition is still very uncertain. Many cases would appear to rest on a neurotic basis, this view being strengthened by the fact that not infrequently the paroxysm can be aborted by pressure on the pneumogastric nerve, by holding a deep inspiration, etc. On the other hand, coronary sclerosis may be present and it can seldom be excluded with any degree of certainty.⁶ The patient here reported gave a typical clinical picture of myocardial disease. Quite possibly paroxysmal tachycardia is merely a symptom that may be produced by different causes, and anatomic changes in the heart muscle may or may not be present. Such also seems to be possible in several other forms of disturbed cardiac rhythm.

THE FORMATION OF URIC ACID.

LAFAYETTE B. MENDEL.

Professor of Physiological Chemistry in the Sheffield Scientific School, Yale University.

NEW HAVEN, CONN.

(Concluded from Page 946.)

THEORIES OF URIC-ACID SYNTHESIS.

Although most physiologists have adopted the theory of the formation of uric acid by an oxidative transformation of purins arising in intermediary metabolism, there is another possible mode of origin which can not be dismissed without due consideration. I refer to the direct synthesis of uric acid. That nucleic acid can be synthesized and the construction of the purin nucleus become possible in mammals is beyond question in the case of developing and growing animals living on a practically purin-free dietary.²⁰ That uric acid itself is

formed by synthetic processes in birds is also verified beyond doubt. In mammals the end product of nitrogenous exchange is quite different, however. When the synthesis of uric acid had been accomplished in the laboratory repeated attempts were made to induce an analogous formation in animals. Horbaczewski's arti-

ficial synthesis from urea $\begin{array}{c} \text{NH}_2 \\ | \\ \text{C} \\ | \\ \text{NH}_2 \end{array}$ and glycooll $\begin{array}{c} \text{NH}_2 \\ | \\ \text{CH}_2 \\ | \\ \text{COOH} \end{array}$ could not be imitated by feeding these compounds; and similar failure in man followed the administration of ammonium sarco-lactate $\begin{array}{c} \text{OH} \\ | \\ \text{C}_2\text{H}_4 \\ | \\ \text{COONH}_4 \end{array}$ and urea which Min-

kowski found effective in producing uric-acid synthesis in birds.

It has been noted in a few cases that the ingestion of considerable quantities of non-nitrogenous foods like fats or sugars may be accompanied by an increased elimination of uric acid. To what extent the conditions for the elimination of uric acid have been modified under such circumstances can not be decided; at most the data admit of a twofold interpretation. The most successful advocate of the immediate synthesis of uric acid in mammals is Wiener,²¹ who has pointed out the twofold source of uric acid in birds—the synthetic and oxidative production—and assumes a similar twofold possibility of formation in mammals under appropriate conditions. The suggestions arose from observations on isolated organs in extracts of which the addition of certain non-nitrogenous compounds, such as tartronic acid and dialuric acid, with and without urea led to an increased formation of uric acid *in vitro*. The theoretic possibilities involved in such a scheme are indicated by the following reactions:

In repeating these experiments of Wiener, Burian²² has noted similar increase in uric-acid formation by tissue extracts in the presence of the non-nitrogenous salicylic, tartronic and dialuric acids. He has shown, however, that this is in no sense due to any synthetic participation by these compounds. When the extracts are devoid of purin compounds no increase in uric acid is observed; the part played by the non-nitrogenous compounds is that of accelerating the oxidation of the purins (xanthin) present. The oxidative mode of formation already explained applies equally well in these cases. We may therefore dismiss the supposed experimental evidence for the assumption of a partial synthetic origin of the uric acid eliminated by mammals.

Various authors²³ have called attention to a further possible genetic relation between the pyrimidin compounds (represented by certain decomposition fragments like thymine, uracil and cytosine of nucleic acids) and uric acid; and from another aspect Knoop and Wind-

haus,²⁴ having obtained methyl imidazol by the action of ammonia on sugar, point out the relation of this compound to the purin nucleus. Such speculations, devoid of all experimental support, are at present of interest only in pointing out the possible roads to a synthesis of uric acid within the body.

Unmindful of the direct evidence of purin oxidation afforded by the enzyme experiments with tissue extracts and emphasizing the difficulty of obtaining uric acid directly from purins in the laboratory with the intervention of animal factors, Kutscher and Seemann²⁵ have ventured another explanation according to which uric acid is the primary product, formed by such synthetic reactions as have just been detailed. A part is in turn reduced, according to Kutscher and Seemann, to simpler purins which participate in the genesis of nucleins in the body; the excess of synthesized uric acid is then either eliminated or destroyed in the usual manner. On this hypothesis the feeding of purins would give rise to increased uric-acid elimination by sparing the synthetic uric acid from reduction, etc., to form nucleic acid and thus inducing a certain excess of it in the system. Experimental evidence of such reduction changes of uric acid to simpler purins is entirely wanting. The capacity of the organism to oxidize purin bases to uric acid, as evidenced by feeding experiments and trials with tissue extracts, remains as the single indisputable fact advanced beyond the realm of hypothesis.

ENDOGENOUS AND EXOGENOUS PURINS.

On a diet free from nucleoproteids and purins, as well as in starvation, the elimination of uric acid and other purin bases does not cease by any means. Under such conditions some metabolic change like the destruction of tissue nucleoprotein must supply the purin nucleus for the eliminated product.

Burian and Schur²⁶ have designated that fraction of the purin output which is independent of ingested purin groups as endogenous in contrast with the exogenous elimination referable to preformed purin complexes in the intakes. They note that on a purin-free diet consisting of such foods as milk, eggs, cheese, potato, rice, green vegetables, wheat bread, butter and sugar, the endogenous uric-acid output is a rather constant quantity for any individual under fixed conditions of living and is practically independent of the total protein or energy content of the diet. With this the observations of Siven²⁷ are in accord. The constants of endogenous purin output vary considerably for different individuals, however, as is shown by additional studies of my co-workers, especially Rockwood,²⁸ and by Kaufmann and Mohr.²⁹ This conception of the different sources of the uric acid eliminated and the determinable endogenous constancy of the individual has been helpful in the study of purin metabolism in both the laboratory and the clinic. For it has enabled the tolerance, or degree of utilization and elimination of purins to be determined with quantitative precision, by estimation of the exogenous uric acid derived from diets of known composition.

Recent experiments by Folin³⁰ and von Wendt,³¹ as well as unpublished observations of my own,³² indicate that the final word regarding the endogenous purin metabolism has not been spoken. When the total amount of protein metabolism is greatly reduced the endogenous output of uric acid is diminished, though this is not the case within ordinary ranges of diet.

URIC ACID AND MUSCULAR METABOLISM.

Some explanation of these discrepancies may be expected in the near future, especially since Burian³³ has lately identified in the muscle purins, notably hypoxanthin, the source of endogenous purins eliminated. He has found that during activity the purin-content of a surviving muscle is increased; and that in the perfusion of muscular parts the circulating fluid carries away uric acid from the muscle both in rest and during contraction. The effective factors thus are the continual accumulation of purins (hypoxanthin) in the muscles, an enzymatic production of uric acid therefrom by the localized xanthin oxidase of the muscle cells and its continuous removal by the blood current. By work the output of uric acid is temporarily increased, though it becomes equalized again in the course of the usual 24 hour period so that an effect of muscular activity on uric acid elimination measured in the daily output has generally been overlooked.

As a tentative hypothesis the conclusion of Burian may be quoted: "From a quantitative point of view the participation of the metabolism of muscles in the formation of endogenous urinary purins in man is probably large. This is made evident, for example, by the fact that the (hourly) endogenous purin output during a condition of muscle fatigue, i. e., presumably diminished hypoxanthin formation in muscle, is sometimes reduced one-half. Obviously only a very small portion of the endogenous urinary purins is derived from the nucleoproteids of disintegrated cells, whereas a very considerable part arises from muscular metabolism. This mode of origin also well explains the behavior of the 24-hour endogenous urinary purin elimination, namely, that it is constant in a single individual even after marked variations in the food intake, provided that the habits of life are reasonably uniform; whereas in different individuals, especially if their musculature is of unlike development, the output may be quite unlike."³⁴

Herein may lie the explanation of the differences in hourly output of endogenous uric acid in the day time and at night. In the later case, during muscular rest, it is always lower, as shown in the following data by Rockwood from a subject living on a fixed purin-free diet. The constancy of the total daily uric acid output is likewise evident.

THE ELIMINATION OF ENDOGENOUS URIC ACID.

The daily diet consisted of:

Milk	1,350 cc.
"Force"	35 gms.
Cream	50 gms.
Sugar	20 gms.
Oyster crackers	250 gm.
Cheese	30 gms.
Eggs	96 gms.
Apple	90 gms.
Wheat bread	25 gms.
Butter	15 gms.
Estimated fuel value	2,770 calories.

SEAT OF URIC ACID FORMATION.

Next in importance to an adequate appreciation of the chemical process by which uric acid originates in metabolism is the recognition of the place where its formation occurs in the organism. Various considerations have been brought to bear on the solution of this question, complicated as it is now known to be by the occurrence of formative and destructive changes simultaneously. Some of the older modes of attacking the problems are readily seen to be fallacious. For example, the fact of the relative abundance of uric acid in particular organs can not properly be explained by any immediate formation of the compound in those tissues, since the result noted may merely be the expression of a temporary deposition in that organ.

The spleen is still regarded in many text-books as an important factor in the production of uric acid, doubtless owing to the original observation by Horbaczewski on the occurrence of this substance in spleen pulp. The observations of Jackson and myself³⁵ on splenectomized animals, and of Gibson and myself³⁶ on a splenectomized man, have shown that the spleen by no means plays a preëminent rôle in purin metabolism, since both exogenous and endogenous uric acid excretion proceeds undiminished in the absence of that organ. In birds the importance of the liver for the synthesis of uric acid has been exhibited beyond question; but it does not assume an equally significant position in mammals, for a considerable excretion of uric acid continues in animals in which the liver is excluded from the circulation by an Eck fistula.

In the classic observations of Hahn, Massen, Nencki and Pawlow³⁷ the output of uric acid was, if anything, found increased after exclusion of the liver—a result corresponding with my own unpublished experiments on various pathologic manifestations of the liver as obtained in the clinic or experimentally induced in animals.³⁸

Experience of this character has long brought the conviction to me that uric acid is formed in various parts of the body—the muscular tissue being prominently suggested—and that the exceptionally large quantities eliminated when the hepatic functions are impaired may be the expression of a deficient destruction of the uric acid formed throughout the body in intermediary metabolism and ordinarily in large part further disintegrated in the liver. The most satisfactory further evidence of the probable unlocalized genesis of uric acid in mammals is afforded by the significant wide-

spread distribution of the enzymes affecting purin metabolism.

Summarizing³⁹ once more the newer observations it appears that especially the spleen, lungs, liver, intestine, muscle and kidney (in some animals at least), are all capable of converting purin bases into uric acid; and that the kidney, muscle and liver can, in turn, further disintegrate the newly formed uric acid—a reaction not accomplished by the spleen or lung. Guanin is first converted into xanthin which is then oxidized to uric acid; while adenin is first transformed into hypoxanthin from which xanthin subsequently arises. An abundant supply of oxygen is essential in every case for the change to uric acid and the catalog of effective or inactive organs is presumably not yet complete. Uric acid formation and destruction by no means always proceed together. The uricolytic or destructive ferment is doubtless principally confined to a few distinct organs, especially the kidney and liver. Differences in the distribution of these active agents unquestionably occur in different species; and the possibility of an elimination, acceleration or retardation of these enzymatic processes by disease or the action of drugs suggests many new problems. At any rate, the newer chemical studies have at length greatly enlarged the horizon of this field of investigation.

RATE OF URIC ACID FORMATION.

The only approach to determining the rate of uric acid formation in man at present consists in observing the rate of elimination—a method the uncertain significance of which has already been pointed out.

Nevertheless, bearing in mind the indefiniteness of the conclusions afforded, it is interesting to note that the curve of endogenous uric acid output from hour to hour tends to attain a level with some slight rise, perhaps, in the morning hours. This has been shown by Dr. E. W. Brown and myself in unpublished experiments, by Pfeil,⁴⁰ by Soetbeer,⁴¹ and by Beebe.⁴²

After purin-containing meals an increased hourly output of uric acid is induced in a comparatively short period, giving rise to a typical curve for the individual. Soetbeer has made the interesting observation that in arthritis urica, the typical curve of elimination after purin-containing meals (meat) may show great irregularity in contrast with that obtained from healthy persons. The typical postprandial rise in uric acid output may, for example, be delayed or missed altogether.

These facts suggest a new method of study applicable to some of the problems of the uric acid diathesis. The influence of drugs like alcohol is brought out in characteristic form by a study of the hourly elimination of uric acid. When no meal is taken even large doses of alcohol fail to produce a marked effect on the hourly

elimination, despite the diuresis which they incite. This is well shown in the following table from Beebe:⁴³

The postprandial rise in uric acid elimination is, however, greatly exaggerated by ingestion of alcohol, especially when a meal rich in purin constituents is taken. The contrast is seen in the following averages compiled from many comparable results by Beebe:⁴⁴

Control Day.		Alcohol Day.

* Meal hour.

Evidently the purin metabolism is noticeably modified by the alcohol absorbed. Bearing in mind the two-fold action—uric acid formation and destruction—which the tissues are capable of, Beebe has interpreted his results to indicate an inhibition of the destructive (uricolytic) phase. The fragmentary data regarding the rate of uric acid elimination have been briefly referred to in this place in order to indicate some of the newer procedures which are being brought to bear on the production of uric acid in health and disease. They contribute little new to the problems with which we have been more directly concerned.

FUTURE PROBLEMS.

Thus I have attempted to subject to a somewhat critical review the more recent experimental observations which should contribute to a better understanding of the formation of uric acid in the body. Its probable endogenous and exogenous antecedents have been considered and the probable chemical reactions involved in the genesis of uric acid from other purin compounds have been detailed. Attention has also been directed to the peculiar rôle of enzymes in both the formation and destruction of uric acid; the organs and tissues concerned, as well as the factors modifying these metabolic changes, have been considered. After all, a résumé serves its best purpose in enabling the scientist to appreciate the limitations of his methods and to learn the true worth of his data, so that from time to time he may formulate his problems more precisely. He thus starts anew in his quest of the truth with better defined aims and a consequent renewal of enthusiasm.

Research brings forth questions as well as answers. The patient reader will have discovered many gaps in the chain of uric acid metabolism, where the missing links remain to be discovered. We assuredly need to know more about the origin and significance of endogenous uric acid. How and why is it modified in such physiologic states as starvation, in growth and in disease—in conditions where "the metabolic processes that determine the uric acid excretion may be said to be in a relatively unstable equilibrium?" What interpretation

shall be given to variations in the endogenous output; and what is the tolerance of the body for purins in diverse conditions? What determines the balance between formation and destruction of uric acid and how do the different tissues participate in its chemical regulation? Are the differences in the purin metabolism of unlike species explicable by qualitative or quantitative considerations? These and many other inquiries at once present themselves; and the patent limitations of our knowledge stimulate the investigator to renewed efforts and awaken his interest.

TREATMENT OF APPENDICITIS IN ITS VARIOUS STAGES AS IT COMES TO THE SURGEON.*

C. H. WALLACE, A.M., M.D.
ST. JOSEPH, MO.

So much has been written and spoken on this subject in the last decade that one might suppose that all had been learned as to its management, but the wide diversion of opinion between the surgeon and internist as to its treatment in general, and the different views maintained by surgeons themselves as to the management of the different stages when encountered, would indicate that many questions are as yet to be settled before the happy mean is reached.

STAGES OF THE DISEASE.

For the convenience of discussion I have divided appendicitis into six arbitrary stages, with very liberal lines of demarcation, as follows: First, inceptive stage, first forty-eight hours; second, rapidly progressing stage, third, fourth and fifth days; third, non-progressing or stationary stage; fourth, interval or chronic stage; fifth, the abscess stage; sixth, the diffuse peritonitis stage.

Before taking up the various stages of appendicitis which I have outlined for my own convenience in dealing with the subject, I believe I am warranted in stating that there exists general satisfaction on the part of surgeons in the gradual and growing realization, both on the part of the general practitioner and of the laity, that appendicitis is strictly a surgical disease and demands surgical treatment at all times at properly selected periods of that time.

This surgical dictum, when first enunciated by surgeons some years ago, met with rather positive resistance on the part of the internist, but with the turning on of the light by operative measures and the exemplification of the true pathology of this affection, error, as it always must, has yielded to the truth, until to-day every educated and up-to-date practitioner admits that therapeutics has no place in the cure of this disease.

First: The Inceptive Stage (first forty-eight hours).—All surgeons are convinced and many internists admit that every patient with appendicitis that comes to a capable physician with proper environment within the first forty-eight hours of the disease should have and is entitled to a curative procedure which will secure for him restoration to health with the least risk of life. The not infrequent experience of every surgeon in encountering the most advanced pathology, a perforated and gangrenous appendix, even in the first or second day, argues the danger of throwing away the opportunity of certainty for one of uncertainty and great hazard to life.

43. Beebe: *Loc. cit.*, p. 20.
44. Beebe: *Loc. cit.*, p. 20.

* Read before the Western Surgical and Gynecological Association at Kansas City.

If clinicians could more often observe the pathology at the operating table, in all its intensity, in some of the mild cases, and in other cases of pronounced symptoms see a pathology limited to the appendix alone and with almost a doubt as to its departure from normal, they would grow more tolerant to operative measures and less wedded to therapeutics in the inceptive stage.

The physician or the surgeon who persuades a patient in the inceptive stage to wait for the interval assumes a responsibility wholly unwarranted, for the interval stage by no means comes to all; in some, opportunity has been knocked and, unadmitted, has gone never to return.

Certainly the physician and surgeon have a common interest in saving the life of the patient, and the study by each of the pathology at the operating table must tend to a mutual conclusion as to the proper management of this disease in its various pathologic stages. This common study, we believe, is gradually growing toward, and will eventuate in, a universal professional belief that all patients with appendicitis if possible should be operated on, if seen by the surgeon, during the first thirty-six or forty-eight hours. The failure to make a diagnosis on the part of the practitioner and the refusal of the family and patient to listen to a reasonable demand for operative measures in the inceptive stage are responsible for almost all the factors entering into the mortality of appendicitis.

Second: The Rapidly Progressing Stage (third, fourth or fifth day).—The stand taken by a few surgeons that the appendix should be removed regardless of the stage of involvement is not in harmony with pathologic process known to be present at certain times of the disease. This is the stage in which experience and experiment have demonstrated that operative measures increase rather than lessen the mortality. It is in this stage that Ochsner enunciated a sound surgical principle: lavage and peristaltic rest by rectal feeding. The facts of its misconception and of its misapplication on the part of the medical profession in general by no means disprove the correctness of his theory. The probably enforced admission that this procedure has resulted in greater harm than good, probably increased the mortality of appendicitis in general in its first years of promulgation, by no means argues its nullification in eventually proving a life-saving procedure. The seizure of this treatment by the opponents to the surgical treatment of appendicitis in general in its application to all cases has proved a curse to humanity and a set-back to the advancement of proper surgical treatment of the disease.

That a better understanding and better education will confine its application to the class of cases intended by the author we believe to be a certainty. That the rapid attacks on Ochsner by some surgeons have been actuated by the commercial sting in the misapplication of his theory by the general practitioner and an apparent lessened number of patients for surgical aid rather than the real scientific difference with him is plausible to a competent and unbiased observer. The admitted honesty of Ochsner, the extensiveness of his clinic for a number of years and the verification of his experience by a large number of other surgeons should be convincing evidence of the correctness of his theory, even if the critic has not the fairness to admit or the clinical material necessary to prove it in his own work.

Operation in this stage usually means rapid extension of the sepsis and death; peristaltic rest means a limitation of the lesion and a day most favorable for surgical intervention. That the duration of this rest period may and is often extended too long is the belief of many surgeons.

Not infrequently cases come to us from the general practitioner with the remark, "I put this patient on the Ochsner treatment; he improved for a time and then had a relapse."

There is a time when Nature totters under her burden and a leak takes place in her fortification, and the case extends into the general peritonitis stage unless the surgeon comes to her rescue at the proper time. Experience and good judgment must decide the time limit in these cases. The extreme position taken by Ochsner in the early promulgation of his treatment by waiting two, three or four weeks I believe to be unnecessary, as Nature will have done all the good in her power in from ten to twenty days.

Third: The Non-Progressive or Subsiding Stage.—Not infrequently an appendicular disease comes to the surgeon with all the symptoms and physical evidence of a subsidence. Reason would indicate that Nature in this case had mastered the situation for the time and would lead to a period of safety if judiciously assisted by rest and a guarded diet. Experience has fully convinced the conservative surgeon to keep hands off and to let these cases drift into the interval period. In these cases the disease seldom shows a tendency to relight into active progress unless the quietude is disturbed by injudicious dietetic measures or ignorant therapeutic applications.

Fourth: The Interval Stage.—This is the stage for self-congratulation for the one who reaches it—an unpromised but fortunate entrance on *terra firma* in the march of appendicular inflammation. This is the stage of sanguine hopes, splendid promises, ideal surgery and happy culmination by surgical operation. If the ideal management of appendicitis were possible, this stage would never be reached. If the surgeon could see all the cases in the inceptive stage there would be no interval stage, there would be no abscess stage, there would be no peritonitis stage and comparatively few fatal stages, but until the family physician the world over follows the lead of such men and internists as Billings, Fitz and Biggs, who favor and teach early operations, surgeons will have to continue to battle against the desperate stages with their uncertain termination.

Fifth: The Abscess Stage.—The patency of an abscess in the right side of the abdomen is convincing evidence to patient, friends and family physician that surgical interference is indicative and imperative. It has been proved within the last two years that the only way of elimination of the appendix from the abdomen is by excision, hence the explosion of the old theory that the appendix sloughed and came away with the pus and debris from an incised and drained appendicular abscess. Recurrence after simple incision, necessitating reoperation and the invariable presence of the original offending organ, has convinced surgeons that to cure appendicitis the appendix must be removed. Another observation worthy of note is the attachment of the appendix in all cases at the line of original incision.

Radical operators like Deaver and his followers, acting on the established fact that cure means removal, advocated and claimed to practice separation of the adhesions and removal of the offending organ in all cases with a low-rate mortality; this procedure, however, has been received with considerable doubt. Many surgeons following the teachings of Deaver, by reason of a large mortality, have been compelled to abandon this radical procedure and many others have never seen their way clear to follow it, but have been content with the simple drainage. Those more conservative and possibly more conscientious practitioners believe in two safe rather

than one dangerous operation in abscess cases. I believe that in all cases of appendicular abscess patients should be told that the first operation is only a preparatory measure for the removal of the appendix at a period not further distant than from five to eight weeks.

Sixth: Stage of Diffuse Peritonitis.—In the past two years greater advancement has been made in the treatment of patients in this than in any other stage. Prior to this time surgeons in general took a pessimistic view of the possible benefits of operative measures, regarding these cases as beyond hope, no matter what the treatment. We now call these cases diffuse or general peritonitis in contradistinction to those in which the patients are moribund. Operation here is left to the feebladder or to ignorant men whose work is a discredit to surgery. The simple application of the natural laws of drainage as advocated by Fowler—that is, keeping the patient in the sitting posture—gave surgeons the cue as to the rational efficacy of operative measures in this particular stage of appendicular disease. Trustworthy reported results of a few surgeons invited trial by surgeons in general, and this gave convincing evidence of the better results that may be attained by more perfected technic in this desperate class of cases. The debatable question here is not operation or non-operation, but the rudeness or tenderness of the aid offered. Shall we simply incise and effectively drain the dependent cavities, or shall we go further and attempt to flush out the offending debris? An investigation of the advocated method shows about an equal division on the part of operators for flushing and non-flushing. In the absence of reliable statistics and confirmation of the greater merits of either method, the individual judgment and experience of each operator must decide whether it is best to foster, to protect and to assist Nature, or by rough fingers to tear away the fibrous exudate and to wash septic material over an unsoiled territory. A limited experience and the careful consideration of the pathologic condition found in this stage leads me to believe that the least manipulation possible means the least mortality.

Medical men, as a rule, believe in the diluting and neutralizing effect of a serous exudate on the toxins of infection and admit that further dilution by salt water may prove beneficial; but why inflict greater trauma to an already wounded peritoneum by flushing when there is an innocent and equally beneficial route of dilution by the application through healthy avenues of absorption? We all realize the circumscribing fraction of a fibrous exudate; why tear down the protecting wall to toxin invasion?

SUMMARY.

I believe, with the mind open for conviction and liable to complete reversal by future advancement, that:

- First.—Appendicitis is always a surgical disease.
- Second.—Every patient should have and is entitled to operative measures within the first forty-eight hours.
- Third.—The rapidly progressing stage is the stage of applicability of the Ochsner treatment, and this offers the lowest mortality.
- Fourth.—Cases coming to the surgeon with evidence of gradually subsiding symptoms, should be deferred to a more favorable operative period.
- Fifth.—Operation should be urged in every interval or chronic case.
- Sixth.—In abscess cases two safe rather than one hazardous operation should be done.
- Seventh.—In diffuse peritonitis all dependent cavities should be carefully incised and drained and not flushed, and, secondarily, the offending organ should be removed.

A METHOD FOR THE CORRECTION OF CICATRICAL TALIPES CALCANEUS.*

A. F. JONAS, M.D.

OMAHA.

The method for the correction of some forms of old talipes calcaneus is illustrated by the two following cases:

CASE 1.—History.—A. B., aged 20, when 4 years of age had the dorsum of the right foot and the lower third of the anterior aspect of the leg severely scalded, producing a sloughing of the skin from the entire burned area. The resulting wound was a long time in healing, which was accomplished by granulation, ending in a dense mass of cicatricial tissues, which in contracting produced an extreme dorsal flexion. After the lapse of several years two different attempts were made to correct the deformity by making a transverse incision, dividing all the soft structures down to the tibio-tarsal joint. The foot was brought down to its normal position. The separation of the wound margins was so great as to produce a large, gaping defect over the dorsum of the foot. In spite of the attempt made to maintain a corrected position of the foot by means of variously constructed devices, the deformity recurred as soon as the operative defect closed over, which it only could do by a process of granulation and cicatricial contraction.

Examination.—At the time of his admission to the hospital the following condition was noted: The right foot was in extreme dorsal flexion and very moderate varus position. The dorsum pedis was nearly in contact with the anterior aspect of

Fig. 1.

Fig. 2.

Fig. 3.

the leg and was held in this position by a thick, dense mass of scar tissue, which seemed intimately adherent to the tibia and the tarsus and metatarsus of the foot. The heel was drawn down so that the os calcis occupied a vertical position and the superincumbent weight was borne on the end of the bone. The posterior portion of the articular surface of the astragalus could be felt under the tendo Achilles. In fact, the backward pressure of the astragalus was indicated by an elevation, making a visible posterior projection against the tendo Achilles. The foot was rigid in the extreme; dorsal or plantar flexion could be made only to the slightest degree. The phalanges were limp and could neither be voluntarily flexed or extended. The deformity was due entirely to a dense cicatricial mass, involving the skin and all the soft structures and including the periosteum to which it was attached. This scar tissue involved an area beginning at the junction of lower in middle tibial third, surrounding nearly one-half of the leg and extending downward to the middle portion of the metatarsus.

Treatment.—After the usual preparation of the operative field the following procedure was adopted: It was evident that a flap must be constructed to cover at least the greater part of the resulting tissue defect, which seemed unavoidable in severing the constricted structures. A pedicle flap, to be turned or twisted so as to fit over the resulting defect in this avascularized tissue, was out of the question. It was evident that a flap with a broad attachment was necessary. The only one available was a triangular flap, so constructed as to cover the tibia astragaloid joint when it should be opened, as it must be, where the scar tissue reached down to and involved the entire

* Read before the Western Surgical and Gynecological Association at Kansas City.

thickness of the joint capsule. Accordingly an incision was made, beginning at the upper end of the scar tissue and extending obliquely downward and outward to the lower end of the outer malleolus (Fig. 1). Another incision was made, beginning as before, but extending downward and inward to the lower end of the inner malleolus. The skin was now seized at the upper end of the incisions and was dissected, including all the tissues, to the periosteum, downward and below the tibioastragaloid joint, creating a triangular flap. The remaining resisting structures over the joint were divided, and with little difficulty the foot could be forced into its normal position. The triangular flap, which was stiff, projected away from the ankle joint like an elongated slipper flap and could not be pressed against the tibial surface nor the joint (Fig. 2). It having become apparent that our flap would be useless unless it could be pushed upward and against the open tibioastragaloid joint, a transverse incision was made over the middle portion of the metatarsus, beginning over the middle part of the first metatarsal and continuing across the foot to the same point on the fifth metatarsal bone. The integument was now dissected from the bones so that the entire flap could be lifted except by its lateral ends, which made it a double-pedicle flap. The flap could now be easily pushed upward so that it completely covered the tibioastragaloid joint, leaving only an inverted V-shaped defect above and a small elliptical wound below (Fig. 3). The wound was now dressed with an aseptic dressing and fixed on a Volkman posterior tin splint. Every portion of the flap healed. About ten days later, when the uncovered portions of the wound had become filled with granulations, a transplantation of Thiersch flaps was made, which very soon completed the healing process. The outcome has been a useful foot with no recurrence of the deformity.

The foregoing method, which is simple and not difficult to do nor a new one, was suggested by a similar procedure in a case of exaggerated talipes calcaneus of congenital origin which came under my care some years previously.

CASE 2.—History.—The case was that of a boy, aged 14. The heel was pointed directly downward, the super-imposed weight was borne on the end of the os calcis. The foot was in extreme dorsal flexion and appeared more like an abnormal appendage than a foot. The contracture of the soft parts on the anterior aspect of the leg was extreme. Efforts at manual correction were entirely ineffectual.

Treatment.—It was determined, under general anesthesia, to do a subcutaneous tenotomy on the unyielding tendons. Accordingly, after the usual preliminary preparations, a subcutaneous section was made of the tibialis anticus, the extensor proprius hallucis, the extensor longus digitorum and the peroneus tertius. This seemed to relieve all the resisting structures except the skin. In attempting to correct the malposition the integument at the tibio-dorso-pedal junction would not yield and, wishing to avoid a skin laceration, a triangular flap with its point upward was dissected away from the anterior tibial aspect, and, reaching downward to an imaginary line extending from one malleolar tip to the other, exposing the ankle joint. The foot was now easily brought into its normal position. This covered the joint completely and extended to a considerable distance above it. An inverted V-shaped defect was created along the lines of incision. This defect was covered one week later with thick Thiersch flaps.

The idea of the use of a triangular flap to correct deformities due to cicatricial or atrophic skin is not new. The possibilities of its use have probably not been fully realized. Experience has long ago demonstrated the uselessness of the transverse incision of the contracted skin. Nothing can be expected of such a procedure, except a speedy recurrence of the deformity by the formation of new scar tissue in the resulting gap. If a triangular flap of sufficient length be created that will not only completely cover the affected joint, but extend a considerable distance above it and then cover with thick Thiersch flaps the resulting V-shaped defect,

we may confidently expect a permanent correction of the deformity. The flap should be long enough. Its point should begin no lower down than the junction of its lower and middle third, and I can imagine cases where it may be advisable to begin the incision over the middle of the tibia. The flap must be long enough so that an elastic covering lies over the tibio-tarsal joint.

The fear that such a flap may slough is not borne out in practice. It is true we sever the return circulation in the skin. We were fearful of such a result in our first attempt and again in our second case, which possessed the additional defect of being illy supplied with blood vessels on account of the cicatricial nature of the flap. In neither case did any part of the flap slough. When the flap is elastic and pliable, as it usually is in non-cicatricial skin, the V-shaped incision is sufficient.

When, however, the flap is cicatricial, stiff and unyielding and will not cover the defect without pressure or tension on it, it becomes necessary to make a trans-dorsal incision, as detailed in Case 1, detach it entirely except on each side, so that the circulation may be maintained. The flap will drop of its own weight against the joint. This procedure constitutes the real and only modification and addition to the old triangular flap method.

It is important that all these flaps fall into position of their own weight; pressure or tension defeats the healing process. The base or flap attachment should be broad. While in both cases the base was directed in a distal direction, it would seem, when possible, the base should be in a central direction on account of the more favorable condition for the venous return. When the triangular flap is used for ankle-joint deformities, the base line should always extend from one malleolar tip to another, (1) because all resisting tendons, ligaments and other resisting structures can be easily severed, (2) because there is no tension in any portion of the flap, (3) because the tibio-astragaloid joint can be exposed and, should it be deemed necessary to do an arthrodesis, as is sometimes required in paralytic or recurring deformity, the articular surfaces can be easily removed with a chisel and an ankylosis of the joint can confidently be expected.

Aims and Uses of a Medical Society.—How often do we find that the man whom we thought from the rumors of disgruntled patients, or envy of rival practitioners to be a man of "hoofs and horns," in reality, when we come to meet him personally, is a gentleman, both professionally and socially. The medical society becomes a clearing-house where we not only acquire new medical knowledge, but also a better and higher opinion of our fellow-practitioners. How easy it is to believe evil of those whom we know only by hearsay or reputation, and how highly do we think of those whom we know the best, and how slow are we to believe slander and gossip about those with whom we are well acquainted. Acquaintance engenders knowledge and sympathy. Sympathy reveals community of interest—community of interest fosters organization, and organization brings power and influence, and this brings me to the consideration of another of the uses of a medical society—namely, its relation to and influence on the community. We have a duty to our patients, but we have a duty to the community in which we live, not only as physicians but as citizens. In sanitary matters, in milk supply, in food inspection, in sewerage and water supply, in education, in our public schools, in municipal improvement and adornment, in the immigration problem, in the care of the dependent and defective classes, the medical society should, and in many instances does, take the leading part in guiding and influencing public sentiment.—A. W. Hurd, in *Buffalo Medical Journal*.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XIV.

STOMACHICS.

In this group we shall include a number of agents, many of them used for centuries, with actions scarcely better understood now than they have been in the remote past. They include those agents commonly called bitters and aromatics, terms which refer only to taste, or, to be more accurate in the case of aromatics, to taste and smell, but which are employed as therapeutic terms for want of better, thus showing how little we know of their mode of action. Despite this want of exact knowledge of their pharmacologic action, the accumulated clinical evidence of 2,000 years or more goes to show that they are useful in slight catarrhal conditions and in minor functional disturbances in which there are no serious anatomic changes.

It is possible that their beneficial influence is sometimes in part due to the psychic effect, as they are agreeable to many tastes, and their regular use may encourage the patient—two important factors in digestion.

Most of the experiments that have hitherto been conducted with these agents have been made on animals, and the results have been variable and often contradictory, hence we must depend almost entirely on clinical evidence for guiding us in their uses.

Owing to the great variability of the functions involved and the natural discrepancy in the capability of various observers, most inaccurate conclusions are reached, and, therefore, no attempt can be made to give precise information as to the exact relative merits of one member rather than another in a given condition.

Bidder and Schmidt, in 1852, observed that the sight of food caused the secretion of gastric juice in a fasting dog, and Pawlow, in 1888, proved the existence of specific secretory nerve fibers in the vagus, and that the gastric secretion is stimulated reflexly from the mouth. That the taste of bitter substances excites the flow of saliva is common experience, and they are said to stimulate reflexly the gastric secretion when they are taken in the mouth. It has not been proved that the bitters have any effect on pancreatic secretion in animals, but it is probable that they do stimulate it reflexly in man.

Borissow has recently studied the effects on gastric secretion in the dog of bitter substances taken into the mouth but not into the stomach. He found that the bitter taste caused a marked increase beginning almost immediately, but not lasting long. He therefore advises that the substance, preferably in liquid form, be given only a short time before eating. He maintains that the negative results obtained by Tschelzow were due to the use of excessive amounts of bitter extract which inhibit the digestive action. Bitter substances which pass into the stomach without producing a bitter taste are useless as stomachics.

Bitter substances in the stomach have been found to increase the number of leucocytes in the blood, and, according to Hofmeister, the leucocytes are concerned in the transportation of a part of the digestive proteids into the circulation. The bitters, therefore, should cause a more rapid absorption of the digested proteids. It can not be stated positively whether or not the bitters increase the gastric movements, but it has been suggested that increased functional activity of the gastrointestinal canal may occur from reflex stimulation, due to irritation of certain sensory nerves in the stomach, in a manner analogous to the reflex stimulation of the gastric secretion by the taste or sight of food.

After therapeutic doses of the simple bitters have reached the stomach they can hardly exert any perceptible effect directly on the activity of the gastric juice, and this extremely slight effect, if adverse, would be very much more than counterbalanced by the increased amount of the secretion.

While there are a number of official substances that may be, and are, used as simple bitters or stomachics, it will not be necessary to enumerate more than a few of the more popular to illustrate the variety and the uses of this class of drugs.

GENTIANA.—U. S.—The dried rhizome and roots of *Gentiana lutea*, constitute by far the best known and the most widely used of all simple bitters. This drug is not alone of interest medicinally, but it has also taken an important part in the folklore, traditions and legends of European peoples. It is said to have been introduced into medicine by Gentius, King of Hlyria, who first discovered its medicinal virtues.

FLUIDEXTRACTUM GENTIANÆ.—U. S.—This is made with diluted alcohol.

Average dose: 1 c.c. (15 minims).

EXTRACTUM GENTIANÆ.—U. S.—This is an aqueous extract of gentian evaporated to pulular consistence.

Average dose: 0.25 gm. (4 grains).

TINCTURA GENTIANÆ COMPOSITA.—U. S.—This represents 10 per cent. of gentian, 4 per cent. of bitter orange peel and 1 per cent. of cardamon in 60 per cent. alcohol.

Average dose: 4 c.c. (1 fluidram).²

CALUMBA.—U. S.—The dried root of *Jateorhiza palmata*, was introduced into Europe by the Portuguese in the seventeenth century and has been much employed as a simple bitter since that time, particularly on the continent of Europe.

FLUIDEXTRACTUM CALUMBÆ.—U. S.—This is made with 70 per cent. alcohol.

Average dose: 2 c.c. (30 minims).

TINCTURA CALUMBÆ.—U. S.—This represents 20 per cent. of the crude drug.

Average dose: 4 c.c. (1 fluidram).

QUASSIA.—U. S.—The wood of *Picrasma excelsa*—Jamaica quassia or of *Quassia amara*—Surinam quassia, appears to be more popular in England than in this country. The official preparations are:

FLUIDEXTRACTUM QUASSIÆ. U. S.—This is made with 33 per cent. alcohol.

Average dose: 0.5 c.c. (8 minims).

EXTRACTUM QUASSIÆ.—U. S.—This is an aqueous extract of quassia, representing ten times its weight of the crude drug.

Average dose: 0.05 gm. (1 grain).

TINCTURA QUASSIÆ.—U. S.—This represents 20 per cent. of quassia in 35 per cent. alcohol.

Average dose: 2 c.c. (30 minims).

Two other drugs which are frequently used by American physicians are *chirata* and *berberis*.

CHIRATA.—U. S.—The dried plant of *Scurreria chirayita* is a comparatively recent addition to European medicine, though it has long been used and held in high esteem by the Hindus. The only official preparation in our Pharmacopeia is:

FLUIDEXTRACTUM CHIRATÆ.—U. S.—This is made with diluted alcohol.

Average dose: 1 c.c. (15 minims).

BERBERIS.—U. S. (Barberry)—The rhizome and roots of *Berberis aquifolium*.

FLUIDEXTRACTUM BERBERIS.—U. S.—This is made with diluted alcohol.

Average dose: 2 c.c. (30 minims).

Aromatics.

Aromatics contain volatile oils, on which they depend for their flavor and for a slightly irritant action on the mucous membranes. Brandt found that the irritation and the consequent hyperemia of the mucous membrane of the alimentary canal, due to sharp tasting substances, caused increased absorption of certain products of digestion. As the aromatics usually have an agreeable taste, they probably increase gastric secretion by reflex stimulation, but it has not been demon-

1. The compound tincture of gentian is probably the most popular of all stomachics and is widely used either alone or in combination with a mild antacid, such as sodium bicarbonate. A mixture that is largely used, particularly in hospital practice, may be compounded somewhat as follows:

R. Tinct. gent. comp.	3x	40℥
Sodium bicarb.	℥r.	xc
Aqua q. s. ad.		3℥i℥ 100℥

To be given in doses of 2 or 3 teaspoonfuls, before meals.

Such a prescription, of course, may be varied in innumerable ways, the addition of compound tincture of cardamon will not alone improve its appearance, but will also make it much more acceptable, in that it makes the whole mixture more aromatic. The addition of tincture of capsicum, 0.2 c.c. or 0.3 c.c. (2 to 5 minims) to each dose, makes the mixture sharp and pungent and may be desirable, particularly in cases of alcoholic gastritis.

strated that they increase the amount of hydrochloric acid or of the digestive ferments.

Gottlieb, in experimenting on rabbits with the volatile oil of mustard and with pepper, found an increased pancreatic secretion, both solids and liquids, from irritation of the gastric mucous membrane. He admits the possibility of the absorption of a part of such volatile substances and a consequent direct stimulation of the secretory cells of the pancreas, but he obtained a similar increase of pancreatic secretion by reflex stimulation, using as irritants 0.5 per cent. acid and strong alkalis, which are not nearly so apt to be rapidly absorbed. Gottlieb's results with volatile oil of mustard have been criticized because he used as much as half a drop for a rabbit—a dose which might be termed massive, considering the size or the weight of the animal, but the rabbit's gastrointestinal canal is probably not so easily irritated as is that of man.

In support of the claim that the pancreatic secretion is reflexly stimulated are the results of Bernstein and Heidenhain's experiments on dogs. These observers found that pancreatic secretion begins so soon as food is taken, when reflex stimulation alone could cause it.

All volatile oils have an antiferment action, and the aromatics, therefore, may lessen gastric fermentation.

The slightly irritant effect, with the hyperemia, must be the main factors in their effects on digestion after that of reflex stimulation, for pancreatic secretion has been found to be much more markedly influenced by the dilation of blood vessels and a consequently free circulation than by changes of blood pressure: thus free secretion has been observed after chloral, with dilated vessels and low blood pressure.

In this connection it is to be remembered that nausea, pain in the stomach and other symptoms of functional disturbances of the gastrointestinal canal are often promptly relieved by external application of heat or even by a mustard footbath, which can only act reflexly.

It is easy to understand why pure air and interesting surroundings play such an important rôle in appetite and digestion when we consider how completely those functions are under the control of the reflexes, mere change of location being much less important than the substitution of interesting for monotonous surroundings, and in advising change of scene with outdoor life these details can not be too carefully considered.

Bitters, and more particularly the aromatic bitters, are indicated in loss of appetite when it is not due to grave gastric disturbances. When catarrh of the gastric mucous membrane complicates the condition, an astringent bitter, such as *serpentaria*, *cinicifuga* or *cinchona*, should be used. In the absence of catarrh, indigestion accompanied by insufficient gastric secretion, a simple bitter, such as gentian or calumba, may be used alone, but it is very much more often advisable to combine the simple bitters with aromatics.

The individual taste of the patient should always be considered in the choice of the aromatic. Men often like simple bitters, such as gentian or gentian and orange, a fact attested by the extraordinary popularity a few years ago of a certain bitters, which consisted practically of compound tincture of gentian. Women usually prefer mildly aromatic and not very bitter substances, while children are generally averse to them altogether.

When excess of acidity exists bitter substances will probably increase the trouble. Just as bitters and aromatics produce a greater effect in cases of functional disturbances, so iron is useful in anemia, though it has little influence in health, and it is often found advisable to combine iron with bitters, in which case the astringents are to be avoided because of the chemie reaction, whereby an inky mixture is formed, disagreeable alike to sight and taste—two great objections in this class of remedies.

Many bitters which are not usually classed as astringents contain enough tannin or similarly acting substances to give inky mixtures with ferrie salts; such, for instance, are gentian and *nuxvomica*. Calumba, therefore, is to be given the preference in all cases in which a bitter is to be combined with a soluble salt of iron. Detannated preparations of cinchona and even solutions of the cinchona alkaloids have little to recommend them in preference to calumba as a simple bitter.

The following is an example of a simple bitter combined with iron:

R. Tinct. calumbæ.....	3iij	100
Tinct. ferri chloridi.....	m.	lxv
Aqua q. s. ad.....	3vi	200

M. Sig.: A tablespoonful may be given half an hour before meals to men, while a teaspoonful will usually suffice for women.²

The possible combinations of aromatic bitters are infinite, and, as previously stated, the individual taste is to be considered rather than slavish adherence to any one formula.

Of the official aromatic bitters we may enumerate:

CALAMUS.—U. S.—(Sweet Flag).—The dried rhizome of *Acorus calamus* was known to the ancients and is still used largely in Europe, though not so popular in this country.

FLUIDEXTRACTUM CALAMI.—U. S.—This is made with 75 per cent. alcohol.

Average dose: 1 c.c. (15 minims).

AURANTI AMARI CORTEX.—U. S.—(Bitter Orange Peel).—The dried rind of the unripe fruit of *Citrus vulgaris* has long been used as an aromatic bitters, but is chiefly used as an addition to other bitter drugs, as in the compound tincture of gentian and the compound tincture of cinchona.

FLUIDEXTRACTUM AURANTI AMARI.—U. S.—This is made with 65 per cent. alcohol.

Average dose: 1 c.c. (15 minims).

TINCTURA AURANTI AMARI.—U. S.—This represents 20 per cent. of the crude drug and contains 60 parts of alcohol.

Average dose: 4 c.c. (1 fluidram).

Astringent Bitters.

Drugs that might properly be classed as astringent bitters are numerous, and, therefore, we shall enumerate but a few of the more interesting or more popular.

CINICIFUGA.—U. S.—The dried rhizome and roots of *Cimicifuga racemosa*, a plant that is a native of North America, have been used extensively in some sections of the United States.

FLUIDEXTRACTUM CINICIFUGÆ.—U. S.—This is made with strong alcohol.

Average dose: 1 c.c. (15 minims).

TINCTURA CINICIFUGÆ.—U. S.—This is made with alcohol.

Average dose: 4 c.c. (1 fluidram).

SERPENTARIA.—U. S.—The rhizome and roots of *Aristolochia serpentaria*, popularly known as Virginia snakeroot, have been used in Europe for over 200 years.

FLUIDEXTRACTUM SERPENTARIÆ.—U. S.—This is made with 80 per cent. alcohol.

Average dose: 2 c.c. (30 minims).

TINCTURA SERPENTARIÆ.—U. S.—This represents 20 per cent. of the crude drug and is made with a menstruum containing 65 parts of alcohol.

Average dose: 4 c.c. (1 fluidram).

HYDRASTIS.—U. S.—The rhizome and rootlets of *Hydrastis canadensis*, a perennial plant that is indigenous to Canada and the United States east of the Mississippi River.

FLUIDEXTRACTUM HYDRASTIS.—U. S.—This is made with a menstruum containing 60 parts of alcohol, with glycerin and water, and should contain not less than 2 per cent. of hydrastin.

Average dose: 2 c.c. (30 minims).

TINCTURA HYDRASTIS.—U. S.—This represents 20 per cent. of the crude drug and is made with 65 per cent. alcohol.

Average dose: 4 c.c. (1 fluidram).

CINCHONA.—U. S.—While undoubtedly better known and more extensively used as a bitter stomachic than either of the above, it is unnecessary to recount the origin or the uses of this drug. It is official under two titles: cinchona and cinchona rubra. Of the former we have:

FLUIDEXTRACTUM CINCHONÆ.—U. S.—This is made with 80 per cent. alcohol and contains 4 per cent. of ether-soluble alkaloids from cinchona.

Average dose: 1 c.c. (15 minims).

TINCTURA CINCHONÆ.—U. S.—This represents 20 per cent. of the crude drug and should contain 0.75 per cent. of cinchona alkaloids.

Average dose: 4 c.c. (1 fluidram).

2. While small doses of iron, well diluted, may be given with bitters before meals, if larger doses are given after eating they are borne better than they would be if given on an empty stomach.

The only official preparation of red cinchona is the old and still popular *Iluxham's* tincture of bark.

TINCTURA CINCHONÆ COMPOSITA.—U. S.—This represents 10 per cent. of red cinchona, 8 per cent. of bitter orange peel and 2 per cent. of *serpentaria*.

Average dose: 4 c.c. (1 fluidram).

For an astringent bitters the fluid extract or the tincture of cinchona, *cimicifuga* or *serpentaria* may be combined somewhat as follows:

R. Fl. ext. cinchona 3xii 50
Tinct. gentiana comp. aa. 3xii 50

M. Sig.: One teaspoonful to be given before meals.

For women it will be well to increase the amount of aromatics, in which case the compound tincture of cardamon may be substituted for the compound tincture of gentian and the mixture even further diluted with aromatic elixir, if thought desirable, as follows:

R. Fl. ext. cinchona 3v 20
Tinct. cardamomi comp. 3v 20
Elixir aromatici, aa. 3x 40

M. Sig.: One teaspoonful of this mixture, with water, to be given before meals.

NUX VOMICA.—U. S.—The dried ripe seed of *Strychnos nux vomica*, although not containing sufficient tannin to be classed as an astringent bitters, is frequently used as a bitter stomachic. The available preparations are:

FLUIDEXTRACTUM NUCIS VOMICÆ.—U. S.—This contains 1 per cent. of strychnin.

Average dose: 0.05 c.c. (1 minim).

TINCTURA NUCIS VOMICÆ.—U. S.—This contains 2 per cent. of extract of *nux vomica* and is assayed to contain 0.1 per cent. of strychnin.

Average dose: 0.6 c.c. (10 minims).²

Carminatives.

The origin of this word is in doubt, some authorities maintaining that it comes from *carmen*, a charm, and the term is even now used somewhat loosely for those agents which produce a sense of warmth and well-being and which act as antispasmodics, or which expel gases from the gastrointestinal canal. When given with cathartics they lessen the griping pain of these drugs, and, being antiseptic, they inhibit the formation of gas by fermentation.

According to the accepted definition, a greater or less number of substances can be included in this particular class. The official carminatives afford a very wide range of choice, as they include practically all aromatic bitters, nearly all the aromatic volatile oils, besides such substances as ginger and capsicum, which contain pungent resinous constituents, alcohol, ether, chloroform and many other agents which produce a sense of warmth when swallowed.

Carminatives are among the most ancient of remedies and are indicated in pain in the stomach or bowels when due to simple indigestion or distention by gas, but not when there is inflammation; in the latter case—for instance, in appendicitis or in peritonitis—carminatives are apt to augment the trouble.

Many of the substances are well known as household remedies and, therefore, it will suffice to enumerate only the more important ones.

ZINGIBER.—U. S.—Ginger has been used from time immemorial in eastern Asia, it was well known to the ancient Greeks, and is even now, perhaps, the most popular of all the carminatives. The most widely used of the official preparations is the tincture.

2. A mixture of *nux vomica* and sodium bicarbonate offers a number of advantages as an efficient and comparatively harmless stomachic. It is made as follows:

R. Tinct. nuxvom. m. lxxx 51
Sodii bicarb. gr. i 150
Aque dest. q. s. ad 5v 150

Although technically this formula involves an incompatibility practically it is very satisfactory indeed. If the mixture is filtered and allowed to stand for 24 hours before being dispensed it will be found to have developed a very pleasant ethereal odor that adds materially to its effectiveness. The usual dose for adults is one tablespoonful before meals. For a patient with chronic constipation the addition of 1 or 2 c.c. (15 to 30 minims) of the fluid extract of *cascara sagrada* will be found to be highly satisfactory. One argument in favor of this combination is that it contains little or no alcohol.

TINCTURA ZINGIBERIS.—U. S.—This represents 20 per cent. of the crude drug exhausted with alcohol.

Average dose: 2 c.c. (30 minims).

FLUIDEXTRACTUM ZINGIBERIS.—U. S.—This is an alcoholic extract.

Average dose: 1 c.c. (15 minims).

OLEORESINA ZINGIBERIS.—U. S.—This is now directed to be made with acetone.

Average dose: 0.03 gm. ($\frac{1}{2}$ grain).

Half a teaspoonful, as noted above, of the tincture may be given in a little hot water or with sugar.

The oleoresin is much more active, and a drop of it may be thoroughly well mixed with powdered sugar and from one-eighth to one-fourth of the quantity given to a child, but not to an infant. It may also be added in half-drop doses or less to bulky cathartic pills or mixtures, but in either case it should be well diluted.

THE OFFICIAL MINTS.

Of the large number of aromatic drugs of the mint family, two have attained more than ordinary popularity as carminatives. The revisers of the Pharmacopœia have, indeed, been impartial in their description of these two substances and have treated them absolutely alike, so that from their status as official drugs it would be difficult to say whether peppermint or spearmint should be accorded the preference. It will be safe to assert, however, that peppermint is the more widely used. It is official as:

MENTHA PIPERITA.—U. S.—(Peppermint).—The dried leaves and flowering tops.

Average dose: 4 gm. (1 dram). This is sometimes used in infusion.

OLEUM MENTHE PIPERITÆ.—U. S.—This is a volatile oil distilled from the fresh and partly dried leaves and flowering tops of peppermint.

SPIRITUS MENTHE PIPERITÆ.—U. S.—This is an alcoholic solution of 10 parts of oil of peppermint filtered through 1 part of bruised peppermint, which imparts to it a distinct greenish color.

Average dose: 2 c.c. (30 minims).

AQUA MENTHE PIPERITÆ.—U. S.—This is a saturated aqueous solution of oil of peppermint.

Average dose: 15 c.c. (4 fluidrams).

As noted above, spearmint, *Mentha viridis*, is official under closely corresponding headings and the doses are, of course, the same.

The uses of these official mints are too numerous and too well known to require description in detail. They appear to be particularly useful in gastric fermentation, for which purpose they are usually given in connection with a mild alkali, like sodium bicarbonate, preferably in the well-known mixture of soda mint of the National Formulary or the widely used soda-mint tablets.⁴

Accumulations of gas in the stomach which prove most distressing can often be promptly relieved by administration of 20 grains of sodium bicarbonate or potassium bicarbonate dissolved, preferably in hot water, to which from 10 to 20 drops of spirit of peppermint or spearmint may be added.

ASAFFETIDA.

ASAFFETIDA.—U. S.—A gum resin obtained from the root of one or more species of *Ferula*, was held in high esteem by the ancient Greek physicians and has been popular with all classes of medical practitioners since that time.

Average dose: 0.25 gm. (4 grains).

As an addition to other carminatives, asaffetida in substance was at one time very popular. At present it is but infrequently administered in any other form than suppositories. These are largely used after surgical operations to overcome the atony and partial paralysis that frequently accompanies surgical in-

4. The mixture of soda and mentha of the National Formulary consists of:

Sodium bicarbonate grs. lxxx 51
Aromatic spirit of ammonia m. l 1
Spearmint water to make 5iij 100

Mix and filter.

The average dose of this preparation is from 2 to 3 teaspoonfuls. Soda-mint tablets as furnished by manufacturers usually consist of 0.3 gm. (5 grains) of sodium bicarbonate with 0.002 (1/30 minims) of oil of peppermint.

interference in the abdomen. The only official preparations containing asafetida in substance are:

PILULE ASAFETIDÆ.—U. S.—Each pill contains 0.2 gm. (3 grains) of asafetida and 0.06 gm. (1 grain) of soap.

Average dose: 2 pills.

TINCTURE ASAFETIDÆ.—U. S. This represents 20 per cent. of asafetida in alcohol.

Average dose: 1 c.c. (15 minims).

EMULSION ASAFETIDÆ.—U. S.—This represents 1 per cent. of asafetida in water.

Average dose: 15 c.c. (4 fluidrams).

This preparation is also used extensively, as a clyster, to relieve accumulations of gas in the intestines, after abdominal operations. It was at one time a very popular remedy for colic in infants, but the nauseous taste makes it very disagreeable and the greater number of infantile complaints, in which it might be indicated, are much more effectively treated with a laxative such as castor oil or magnesia, and by the application of heat to the abdomen.

The pernicious habit of using such preparations as Mrs. Winslow's Soothing Syrup, Chamberlain's Colic, Cholera and Diarrhea Remedy, Kopp's Baby Friend⁵ and others which have been exposed in THE JOURNAL, can not be too strongly condemned. If an opiate is thought to be necessary, it is much better to advise the nurse or mother to give five drops or more of paregoric, with warnings about the disadvantages and the dangers of its indiscriminate use.

CHLOROFORM AND ETHER.

CHLOROFORMUM.—U. S.—As a carminative, chloroform probably deserves a much more extended use than it now has.

Average dose: 0.3 c.c. (5 minims). This may be given either on sugar, in shaved ice, or in ice-cold water.

SPIRITUS CHLOROFORMI.—U. S.—This contains 6 per cent. of chloroform in alcohol.

Average dose: 2 c.c. (30 minims).

EMULSUM CHLOROFORMI.—U. S.—This contains 4 per cent. of chloroform with a small proportion of expressed oil of almonds, emulsified with tragacanth.

Average dose: 8 c.c. (2 fluidrams).

The spirit of chloroform, diluted with aromatic elixir, or the emulsion of chloroform given alone, promptly affords a sense of warmth in the stomach and will usually give relief in cases of colic and pain.

ETHER.—U. S.—Ether, sulphuric ether of the early pharmacopœias has long been in use as a carminative.

Average dose: 1 c.c. (15 minims).

SPIRITUS ÆTHERIS.—U. S.—This contains about 33 per cent. of ether.

Average dose: 4 c.c. (1 fluidram).

SPIRITUS ÆTHERIS COMPOSITUS.—U. S.—The well known and widely used Hoffmann's anodyne contains in addition to ether about 2.5 per cent. of ethereal oil.

Average dose: 4 c.c. (1 fluidram).

Compound spirit of ether, in addition to its other uses, has long enjoyed a special reputation in hysteria due to gastric disturbances. It is disagreeable to the taste, however, and probably possesses no advantage over hot whisky and water, or spirit of nitrous ether.

Alcoholic liquids in general are often useful, but their use and their numerous disadvantages can not be advantageously discussed in this connection.

CLOVES AND OTHER AROMATIC SUBSTANCES.

CARYOPHYLLUS.—U. S.—(Cloves.)—The dried flower buds of *Eugenia aromatica*. This remedy appears to have been known to the early Egyptians, but was not known to or used by the later Greeks. In Europe this drug, probably introduced by the Arabians, has been known for many years.

Average dose: 0.25 gm. (4 grains).

OLEUM CARYOPHYLLI.—U. S.—This is a volatile oil distilled from cloves.

Average dose: 0.05 c.c. (1 minim).

The oil of cloves is much more frequently used for its anes-

thetic and caustic effect on exposed nerves in carious teeth than as a carminative, but it may be used for the latter purpose, in which case it is better to add it to spirit of peppermint or some other alcoholic carminative preparation, before diluting with water.

Oil of cinnamon resembles oil of cloves in its carminative effect, and the official tincture of cinnamon is also useful for the same purpose, but is more commonly employed as an adjuvant or flavor for other more active carminative agents, and in diarrhea.

Mustard, pepper and nutmeg are not used medicinally as carminatives, but are much employed as condiments to serve practically the same purpose.

Clinical Notes

IDIOSYNCRASY TO LEAD-WATER AND

LAUDANUM.*

ALBERT ENGLES BLACKBURN, M.D.
PHILADELPHIA.

My attention was first called to this condition some six years ago, when a solution composed of Goulard's extract and tincture of opium, of each 1.5 oz. to a quart of water, was ordered to be applied warm to a knee which had been injured by a fall. In twenty-four hours a diffuse erythema with intense itching and burning developed over the area to which the solution was applied. The patient complained more of this than of the injury. The second instance was as follows:

The patient was a corpulent woman who was suffering from a very much inflamed leg of varicose origin, which threatened to break down and form an ulcer. The above solution was applied in the same manner. Again in twenty-four hours, when I next saw her, there was a very pronounced erythema, corresponding to the part to which the solution had been applied. The patient complained of burning and itching. When I saw her on the following day the surface was thickly studded by vesicles and pustules, which infection had probably been introduced by scratching. By this time the poison had been carried to the eyelids, forehead and cheeks, which became swollen to the point of disfigurement, with the itching and burning very intense. The condition lasted about ten days, when it dried and desquamated.

Some three months ago I was called to see the same patient, who was suffering from acute articular rheumatism involving the right wrist. The same solution was ordered and the same phenomena were observed.

In the first instance the druggist was thought to have made a mistake, but this I knew positively was not the case in the last instance. The only solution was idiosyncrasy on the part of the patient. Whether it was caused by the lead-water or the laudanum I do not positively know. Some of those I have spoken to about the subject think it due to the first and others to the second.

Poisoning from the external application of either or both of these must be exceedingly rare, as in a search which included a number of textbooks, the *Index Medicus* and the library of the college I failed to find reference to the subject.

J. C. White, of Boston, in his "Dermatitis Venenata," does not mention it. Morrow on "Drug Eruptions" does not allude to poisoning by lead when applied externally, but does allude to its producing an erythema when taken internally. I quote from him the following:

* Read before the West Philadelphia Branch of County Medical Society.

The external application of the salts of lead in the form of solutions and ointments sometimes produces discoloration of the skin of a brownish or black character.

Foucaud de l'Espagne reports the case of a woman who was ordered a eytrate of lead as an eye wash; under the advice of another physician she was at the same time using sulphur baths for rheumatism. A black discoloration of the eyelids ensued and spread over the cheek bones, which was removed after six days by bathing the parts with infusion of herbs.

The internal administration of the salts of lead may cause an erythematous rash of the skin.

Snow, quoted by Peffard, reports a case where the body became spotted by petechiae from the internal use of carbonate of lead.

3726 Baring Street.

ACUTE ACETANILID POISONING.

JOHN BOYD TYRRELL, Sc.M., M.D.
SAN FRANCISCO.

C. H. M., male, aged 52, came to this city from his home in Idaho to visit relatives. While here he complained of severe headache most of the time. Not getting relief from ordinary "headache pills" and "headache powders," he went to one of the local drug stores and bought an ounce of acetanilid in powder, bulk, took it to the hotel at which he was stopping, and took what he said was a half teaspoonful. He was relieved of his headache in a short time, and in about two hours went down town to do some shopping. As he was walking down town he noticed that he was weak, but paid no attention to it. He went into a barber shop for a shave, and scared the barber by his "terrible blueness," as the barber expressed it to me afterward. However, the barber shaved him, and felt very much relieved after the man had left the shop.

From the barber shop the patient went to a clothing store, where one of the clerks noticed his condition. In a few minutes he was seen to sway, become extremely cyanotic, and go to the floor in a "dead faint." I was immediately called and found him in deep syncope, extremely cyanotic, and with pulse very feeble and rapid.

I gave him strychnia, digitalin and nitroglycerin in combination; also artificial heat and fresh air, and resuscitated him. In about three minutes he went into another attack of syncope. I again gave him nitroglycerin, gr. 1/100, to which his heart responded, and kept him quiet for several hours, during which time he had several slight attacks of syncope. Patient gradually recovered.

I believe that acetanilid poisoning is more common than is usually believed, due to the laxness of laws regulating the sale of such products, and especially the sale of the nostrums containing this treacherous drug as their principal ingredient.

THE ADAMS-STOKES SYNDROME AND THE BUNDLE OF HIS.

E. O. JELICK, M.D.; C. M. COOPER, M.D.; WILLIAM OPHULES, M.D.
SAN FRANCISCO.

We desire to put on record a case of acute epididylitis, probably gonorrheal in origin, leading to septicemic symptoms, in the course of which the Adams-Stokes syndrome appeared fourteen days before death. The autopsy of the heart demonstrated anemic necrosis of the muscular septum in the region of the bundle of His consequent on a recent thrombosis of its nutrient arteries. Elsewhere the heart muscle was healthy.

New Instrument

A NEW UTERINE DILATOR.

FREDERICK LEAVITT, M.D.
ST. PAUL, MINN.

To open the mouth and neck of the pregnant uterus artificially is difficult under favorable conditions; to do so when the conditions are unfavorable is one of the most trying operations in all surgery.

Under some conditions of the os and cervix, manual dilatation is more or less easily accomplished, but there are other cases in which the fingers are utterly useless. Consider the tissues to be overcome—a fibromuscular canal so firmly closed normally that with all the burdensome pressure of gravidity it remains intact, even the force of strong labor causing it to yield only after many hours of exhausting effort. If it takes Nature ten or fifteen hours to effect an opening, what shall be said of a device that will accomplish such a feat within an hour and do it safely?

While the hand is a dilator always at command there are disadvantages accompanying its use. First, it can not be thoroughly sterilized; and, second, it will tire. The frequent alternate use of both hands, with an assistant's hands brought into service in tedious and difficult cases, multiplies the chances of infection. Manual dilatation, therefore, is a truly surgical procedure.

The dilator I have devised is an instrument of four levers and a handle with a large fulcrum on one end and a smaller one on the other. Each blade is notched near its middle, and when placed in position for dilating, the notch fits into a suitable depression on the edge of the fulcrum. The ends of the levers—the blade part—are designed to enter the cavity of the uterus only so far as may be necessary for the work to be accomplished. The gynecic end is long and slender, the obstetric end short and broad. During pregnancy, particularly toward its close, there would be no difficulty in introducing the broader ends of the levers, since they may be introduced one at a time. Dilatation may be carried on by compression with the hands alone, with the rubber alone, or, what is very practical, with manual and elastic force, both applied at the same time, the one supplementing the other. If intermittent pressure be desired, opposing blades may be compressed even while the rubber is doing its part of the work.

The instrument is simple in construction. There are no screws or nuts to adjust; there are no hinges or joints to become rusty; no detachable parts to get lost. There are only five pieces to the whole instrument, and they are very plain and easily cleaned. It is self-retaining as soon as the second blade is in position. It is light, yet strong enough to do twice the work demanded of it. It does not obstruct the field of operation. The process of dilatation may be closely watched, the parts sponged, and the presenting part palpated—all between the blades of the instrument. If occasion demands great haste, this also permits the making of multiple incisions into the cervix after the method of Dührssen. The degree of dilatation is approximately that of the hand, i. e., eight and one-half inches in circumference. For all practical purposes this is deemed sufficient.

The manipulation of the device is easy. The patient is brought to the edge of the table and the knees supported in the lithotomy position; the posterior wall of the vagina is depressed with a speculum. The Edebohl speculum is very serviceable, as it is self-retaining when weighted, besides, it dilates the outlet of the parturient canal. The first blade of the dilator is introduced up to the shoulder of the blade (Fig. 1). On this is placed the fulcrum of the handle, the notches fitting into each other (Fig. 2). The second blade is introduced similarly and should be placed opposite the first one. A small rubber band (Fig. 3) is now slipped over the free ends of the levers, in order to keep them in position. The two remaining blades are placed in apposition, the rubber band slipped over each as it is put in place (Fig. 4). When all four blades are properly adjusted (Fig. 5), active dilatation is begun and maintained by winding around the ends of the levers one or

1. In this connection see editorial in THE JOURNAL, March 3, 1906, page 658.

more rubber bands. These are not slipped over the blades as was the smaller one, but are wound around them. To do this dextrously the band is looped over any one of the blades, put on the stretch, and carried around once, twice, thrice, as the

Fig. 1.—Introducing the first blade.

Fig. 2.—The first blade in position, the fulcrum adjusted to it and ready to receive the second blade.

Fig. 3.—Slipping a rubber band over the proximal ends of the levers (calculating from the operator) already in working position.

Fig. 4.—Adjusting the fourth and last blade.

case may be, the other end being made fast by slipping it in turn over any one of the blades. Any good rubber band of average size is competent to dilate the os uteri in a reasonably short time—say, thirty to forty-five minutes. As dilatation progresses (Fig. 6) and the ends of the levers are brought together, the band may be loosened and reapplied—take an

Fig. 5.—All the blades in position and held in place by a rubber band. Active dilatation is begun and maintained by means of a rubber band of average size and strength. As dilatation progresses, the band may be released and re-applied, each time fastening the free end a little further around.

Fig. 6.—Showing the amount of dilatation possible when using the larger or obstetric end of the handle.

Fig. 7.—The levers in position for dilating the cervix for gynecologic purposes. The rubber band near the fulcrum is simply to hold the blades in place on the handle. After dilatation has progressed sufficiently, the third and fourth blades also may be applied if desired.

extra turn—or another band may be used to supplement the first one (Fig. 7).

The instrument has been used in St. Paul during the past year and a half with success that warrants its recommendation.

125 Lowry Arcade.

New Appliance

A NEW REAGENT OUTFIT FOR CLASSES IN BACTERIOLOGY.

E. GUY HOPKINS, M.D.

Lecturer on Bacteriology and Demonstrator of the Microscopical Laboratories, University College of Medicine, Richmond, Virginia, and Clinical Pathologist of the Virginia Hospital.

RICHMOND, VA.

In order to meet the requirements of economy, simplicity and neatness I have devised the reagent outfit here illustrated for the use of my classes in the microscopic laboratories of the University College of Medicine, Richmond, Va.

This outfit consists of a tube rack and a set of reagent containers (Fig. 1).

The rack consists of a block of wood 2x2x6 inches, bored with 12 holes $1\frac{1}{2}$ inches deep by $\frac{3}{4}$ inch in diameter.

The containers consists of 12 small test tubes, 100 mm. long by 8 mm. inside diameter. These tubes are equipped as follows:

Figure 1.

One is fitted with a cotton mop and contains vaselin for sealing hanging-drop preparations. Three are fitted with ordinary cork stoppers and contain respectively, alcohol, acetic-acid-alcohol, xylol. Eight have pipette points attached to their mouths by means of rubber tubing 35 mm. long, 7 mm. outside diameter and 5 mm. inside diameter; the pipette points are 20 mm. long and are drawn from 6 mm. glass tubing; these tubes contain respectively: distilled water, Gram's solution, 1 per cent. sulphuric acid, Bismarck brown, Loeffler's methylen blue, carbol-fuchsin, Gabbett's solution and anilin-gentian-violet.

Each container is supplied with enough solution for from 15 to 20 coverslip preparations. When in use the container is inverted over the coverslip and the rubber is compressed between the finger and thumb until the desired amount of fluid has been expelled. Relaxation of the rubber then causes re-entrance into the tube of any fluid adherent to the point, so that there is no leakage down the side when the container is replaced in the rack (Fig. 2).

If it is undesirable to leave a container open, even by so small an aperture as the point of the pipette, it may be effec-

tively closed by folding the pipette point back against the side of the test tube and confining it there by a small rubber band, thus making a stopper of the rubber tube.

When the containers become empty they are refilled from stock bottles fitted with siphons. These siphons have long pointed distal limbs, so that in filling a container it is necessary to remove only the pipette point from the rubber tube, which remains attached to the test tube (Fig. 3).

Figure 2.

Figure 3.

After a critical experience with this outfit, covering a period of three months, with a class of 76 students, I find it admirably adapted to the purpose for which it is designed.

The same principle with slight variations has also been applied in preparing outfits for other laboratory classes.

SATURDAY, MARCH 31, 1906.

THE PHYSICIAN AND PSYCHIC TREATMENT.

All through the history of medicine it has been recognized that the influence of suggestion plays an important rôle in therapeutics. The physician's assurance with regard to the significance of symptoms and as to the prognosis of the case has always been acknowledged as distinctly curative in tendency. Suggestion, however, has always been considered of secondary importance, and in the organic affections this is especially true. In recent years there have been many developments pointing to the therapeutic influence of the mind over the body whenever suggestion can be used with good effect, especially in regard to so-called functional conditions. Nearly a century ago Mesmer claimed that a number of presumably serious symptoms could be effectively cured by suggestion either in the hypnotic condition or in the waking state. In more recent times the success of mental healing and of Eddyism has called renewed attention to these facts. The frequently announced new remedies that prove after a time to be not so effective as was at first thought, because their novelty has worn off, provides further confirmatory evidence of the therapeutic value of suggestion.

During the past decade a number of contributions to practical therapeutics have been made that recommend the use of suggestion, not as a merely secondary and accessory method of treating certain functional diseases, but deliberately, as an independent therapeutic agent. Two valuable contributions of this kind have recently appeared. In the last volume of "International Clinics,"¹ Dr. Pallet, physician to the Paris hospitals, directs attention to psychotherapy in nervous diseases. He emphasizes the undesirability of using hypnotic suggestions in most of the functional neuroses, since not infrequently it leads to a further weakening of the will and a consequent loss of control over nervous conditions. He has found, however, that ordinary persuasion and rational discussion of symptoms with a patient will often prove sufficient to remove symptoms that have been a source of suffering for a long period. Dr. DuBois,² professor of neuropathology at the University of Berne, Switzerland, has published a book,

which we reviewed recently, in which the proper use of psychic treatment for nervous diseases is systematically considered.

Both these authorities have picked out certain underlying conditions which are causative of nervous symptoms and which they have found amenable to psychic treatment. The most important of these are the fixed ideas and the so-called phobias or fears which often prove sources of so much worry to patients as to bring about extremely annoying and persistent symptoms. Fixed ideas are especially likely to rule over the digestive tract and must be removed before any of the many forms of neurotic dyspepsia can be lastingly improved. Patients become convinced that they can not take certain kinds of food or that beyond a certain quantity their digestive organs are unable to dispose of it properly, and then a whole round of symptoms is likely to develop, because of the lack of nutrition consequent on food limitation. More is accomplished by carefully removing such fixed ideas than by the administration of the most nicely adjusted digestive remedies or the use of the most powerful ferments and enzymes to aid the ordinary ferment processes.

Phobias are especially likely to affect the heart and the cerebral circulation. Two very important sets of symptoms develop as a consequence. The heart palpitations of neurotic patients constitute one of the most important sets of symptoms with which physicians have to deal. Pseudo-angina-pectoris, with positive pain in the precordia and a sense of impending death, occurring in young persons without any signs of arterial degeneration or any symptom of a heart lesion, is the worst of these, but the symptoms may exist in minor degrees down to simple palpitation. Not infrequently the sleep is disturbed as a consequence of the patient's solicitude with regard to the possible consequences of these symptoms, and the result is another element in the vicious circle that gradually undermines the patient's physical condition. Insomnia itself in its varying forms, probably due more to disturbances of cerebral circulation than to any other single cause, comes under the same head and is often rendered persistent by the patient's anxiety as to whether or not he will be able to sleep, and his constant fear lest his loss of sleep should eventually lead to intellectual deterioration and perhaps to insanity.

Any physician of experience knows how difficult it is to treat such patients by any of the ordinary remedial measures. He is aware, also, how often such conditions are improved by the changed state of mind consequent on a series of interviews with a mental healer or the suggestive influence of some one who has insisted with authority that the condition can surely be cured. The deliberate use of persuasive suggestion in these cases is recommended by Ballet and DuBois as the most efficient remedy and one whose influence will persist longer than any other method of treatment. The suggestion

1. International Clinics, Fifteenth Series, vol. IV, 1905.

2. "The Psychic Treatment of Nervous Disorders," by Dr. Paul DuBois, translated and edited by Dr. South Elly Johnson, and Dr. William A. White. New York. Reviewed in THIS JOURNAL, March 16, 1906.

may have to be repeated on a number of occasions, but if the physician can assure his patient that there is no organic lesion of heart or brain, either existent or impending, then improvement is usually a matter of only a short time. There seems to be no doubt that the deliberate use of this method of psychotherapy would add a new and efficient therapeutic agent in the treatment of what are usually very obstinate cases.

Its more general employment by the general practitioner would lessen the number of patients who now tire of the consumption of drugs from which no benefit is derived or from which only temporary relief is obtained, and who eventually find their way at the present time into the hands of quacks and charlatans of various kinds. All physicians employ suggestion to some degree, but there is room for its employment to a much greater extent and in a wider field with benefit to rational medicine, to physicians and to their patients.

DRINKING IN GREAT BRITAIN.

The drink bill of Great Britain is enormous, and drinking among women is reported to be more prevalent than ever, though statistics show that excessive consumption of alcoholic beverages is on the wane. In fact, it would seem that "a wave of sobriety" is at last passing over that country.

Dr. Dawson Burns, in a recent communication to the *London Times*, compares the expenditure on alcoholic liquors for 1905 and 1901, respectively, and finds a decrease of no less than \$24,050,000. This is a substantial decrease, but as the total amount expended on drink still reaches the immense sum of \$820,000,000, more or less, there is ample room for further improvement in this direction. Undoubtedly the drinking habits of the population at large of Great Britain, and especially of town dwellers, are responsible for much of the physical and mental degeneration which are now obvious features in the large centers of population throughout the United Kingdom. Efforts are made to minimize the significance of the conditions of urban life, but it seems to be acknowledged that insanity is on the increase and has been making rapid headway for the past thirty years, and that the race has deteriorated physically and mentally. Such decadence must be attributed, in great part at least, to the tendency of the population to desert the country for the towns, in consequence of which the towns are overcrowded and present in most respects conditions of life inimical to sound health. And of all the agencies prejudicial to health which beset the dwellers in cities, none has so deadly an effect on the body and mind as has strong drink.

It must be reassuring to our British cousins to find that their drink bill is showing a steady and continuous decrease. The total diminution in expenditure on drink in six years has been nearly \$410,000,000, or, allowing for increase of population, in the neighborhood of \$170,-

000,000. The reasons for this comparative and continuous tendency to more temperate habits among the British can not be stated off-hand. Perhaps "hard times" has had much to do with the "wave of sobriety," although it is asserted by many who are in a position to know whereof they speak that the somewhat altered situation is due to a diminished desire for alcoholic beverages. It is to be hoped that the latter explanation is the correct one, and that the people of Great Britain are beginning to recognize the folly of their ways and to appreciate the fact that drink has already sapped, in some degree, the vitality and energy of the race, and that unless the habit be checked matters will go from bad to worse. Dr. Burns calculates that the expenditure for drink per capita in England is nearly \$20, in Scotland slightly more than \$15 and in Ireland even less.

Without seeming to be pharisaical and thanking God that we are not as other men are, we may lay the flattering unction to our souls that as consumers of strong drink we are far behind our European brothers. These remarks, however, must apply to the country as a whole. In many of the cities, so far as the drink question is concerned, conditions approximate those that exist in European cities. Even in the cities we are greatly in advance of Great Britain in all that concerns the hygiene of saloons. The *Lancet* recently published articles dealing with the "public house" as a factor in the spread of disease, in which was pointed out the unsanitary state of affairs as regards the ordinary British saloon, and a contrast was drawn between this class of establishments there and here, which was greatly in favor of the American saloon. The employment of barmaids was also made the subject of a scathing editorial in a later issue of our *London contemporary*.

In this country we are at all times, perhaps, too ready to "pat ourselves on the back" with regard to the superiority of our institutions generally, but when a conservative journal like the *Lancet* acknowledges that in the management of saloons, regarded from a sanitary standpoint, the United States easily leads, we may be allowed to plume ourselves on our progress without laying ourselves open to the charge of being unduly impressed with the manifold advantages of our own land and institutions. The drink problem is undoubtedly the most serious that confronts the inhabitants of Europe, leading, as it does, to the loss of physical and mental vigor. Here the question may be of lesser import, but it is one that can not be lightly regarded.

THE EFFECT OF ROENTGEN RAYS ON THE BLOOD FORMING ORGANS.

At first there was a tendency to deny or to doubt that the Roentgen ray had any special effect on internal organs or processes, but two practically simultaneous yet independent events showed that this assumption was wholly without foundation. The first of these events

in point of time was the observation of the remarkable effect of Roentgen rays on the course of pseudoleukemia and leukemia (Pusey, Senn, Brown and others), to the treatment of which they were applied in a more or less empirical way. The second event was the demonstration by Heinecke (1903-4) of the elective destructive action of the rays on the lymphoid tissues in the spleen, lymph nodes and bone marrow.

In this country the effect of the Roentgen rays on the blood-forming organs has been studied especially by Warthin,¹ who combines experimental work with the study of material from leukemic patients treated with Roentgen irradiation. His experimental work shows that the rays cause nuclear disintegration and necrosis of lymphoid, myeloid and epithelioid cells in small animals after very short exposures and commonly most marked in the spleen. This destruction may be succeeded by regenerative processes that may pursue a protracted course. Exposures of five hours kill mice, rats, rabbits and guinea-pigs after a few days, the symptoms permitting the interpretation of an intoxication from disintegrative processes in cellular protein material.

The selective effects of the Roentgen rays demonstrated by Heinecke, Warthin and others explain the therapeutic action of the rays in leukemia—it is due to removal of leucocytes from the general circulation, the spleen, etc.—and to delay in the production of new cells. The final result to be obtained by this treatment is still a matter of some uncertainty, and it seems doubtful whether or not the underlying and essential causes can be totally removed. The leukemic state may be resolved into an aleukemic one (Warthin's Case 1) "or it may even assume the type of a sarcoma" (Warthin's Case 3). The destruction of enormous numbers of leucocytes by this treatment is in itself dangerous, because of the formation of neurotoxic and other poisons and because of grave changes in the kidneys, characterized especially by extensive calcification, due to excretion of poisonous substances, as shown well in Brown and Jack's original case (Warthin's Case 1). As put by Warthin, the problem resolves itself into this: "How much of the abnormal leucocyte-forming tissue in the bone marrow, spleen or lymph glands can be destroyed by Roentgen rays before the patient succumbs to the disease or to the treatment"? He suggests that in early cases a cure may be effected.

This situation calls for continued investigation in the hope that some means may be discovered that will render this at first so promising a treatment for so hopeless a disease as leukemia really effective and practicable. Thus the mechanism of *x*-ray destruction of leucocytes is yet wholly obscure. Investigation by Capps and Smith,² as well as others, shows that there develops a neurotoxic substance in the blood of leukemic patients treated with Roentgen irradiation, whose serum on in-

jection into other patients promptly reduces the number of leucocytes.

The data at hand concerning this substance are yet too few to permit of much speculation concerning its nature and other qualities. Suffice it to say that in the Roentgen ray we have an agent with special action on the leucocytes and blood-forming organs and that the continued study of this effect from various points of view certainly will yield important results as regards the diseases that affect these organs.

THE ARMY MEDICAL REORGANIZATION BILL.

The leading editorial in the *Army and Navy Journal* for March 10 comments on the inexplicable action of Senator Hale of Maine in his opposition to Senate bill No. 1539, to increase the efficiency of the medical department of the United States Army, a bill the urgency of which is acknowledged not only by the medical corps, but by the line of the army. THE JOURNAL has repeatedly referred to the necessity of the passage of this bill which deals with a question of vital importance to the entire military service. In the editorial it is stated that "it is an amazing and disheartening thing . . . that a bill now pending in the Senate, which seeks to correct the admitted deficiencies in the Medical Department of the United States Army, should encounter an unreasonable and indefensible opposition at the hands of a distinguished Senator—Mr. Hale of Maine. . . . Ever since the anxious days immediately preceding the outbreak of the Spanish war he has maintained an attitude of obstruction toward nearly every important measure relating to the national defenses."

The bill was passed by the Senate February 5, but Senator Hale, who was not present at the time, later demanded that the bill be reconsidered, and, in conformity with senatorial courtesy, this was done and the bill was restored to the calendar. It came before the Senate again on March 6, where it met a most arbitrary and irrational opposition from Senator Hale, and the measure went over. Without seeking to fathom or to impugn the motives of the Senator for endeavoring to defeat this just and humane measure, it is evident that he is entirely in error in the attitude which he has taken and is engaged in an effort to inflict on the army, and indeed on the whole country, what would be, in the event of war, a stupendous calamity.

The present faulty condition of the medical department of the army has existed for more than five years, notwithstanding continuous efforts for its correction made by high officers of the government who have thoroughly studied the situation. Last year the Senate passed the bill and the House was in favor of it, but for some unknown reason it was blocked by the speaker. This year, in the House, the same bill is now before the Military Committee and a favorable report is anticipated.

1. International Clinics, 1906.

2. Trans. Chicago Path. Soc., 1905, vi, 371.

There are three vital defects in the organization of the medical corps: 1. It is numerically inadequate to meet the needs of the army as it is now on a peace basis of 60,000 men. In other words, it lacks one-fourth the officers required during peace. In the event of war the army would be at once expanded to a strength of 100,000 men, when, it is obvious, the medical personnel would be entirely insufficient for the humane work required of it, and the country again would be obliged to witness the tragedy of pest-stricken camps and the ghastly spectacle of multitudes of deaths from preventable diseases. The question with any nation having world relations is not "Will war come?" but "How soon will it come?" When it does come—as come it will—we want a sanitary and medical service that will meet the needs of the time. The work of preparation must be done during peace. When the war cloud looms, it will be too late, and inadequate preparation is almost as bad as none. Inertia and delay to provide those safeguards which experience has so plainly pointed out as necessary to the efficiency of our army savor of barbarism. We have recently seen what a small nation just out of its swaddling clothes can do by enlightened action in the way of mitigating the havoc wrought by disease in war time. Are we who boast of being at the forefront of civilization to be outdone in this work of humanity by the baby of nations?

II. There is a glaring inadequacy of rank. There is less rank relatively in the medical corps to-day than in any other staff corps in the army, although the difficult and exacting duties of the department render such discrimination against it most unjust and prejudicial. To-day there are twenty-seven vacancies in the medical department, in spite of the utmost endeavors of the Surgeon-General to induce a sufficient number of candidates to take the examination. Until an appointment in the medical staff shall hold out greater inducements to the qualified young physician, it will be impossible to fill the medical corps.

III. The contract surgeon system, which Mr. Hale defends, has been an incubus on the medical department for fifty years, and is now without a single redeeming feature to justify its continuance. It has been at best but a makeshift, and under present conditions is archaic and unsatisfactory. It is true that excellent service has been rendered by many of the contract surgeons, but the system is absolutely out of place in the military service.

The bill proposed by the Surgeon-General aims to correct these defects. It is conservative, its provisions have been deeply considered and it barely meets the needs of the army. It has the hearty approval of the President, the Secretary of War, the Secretary of State, the General Staff, the press of the country in general, and the medical profession. Why has it not been passed?

It is most unfortunate that the body possessing the power to remedy the defects spoken of has in it no

specialists in any line affecting health. Perhaps for this reason it is not specially interested in the health of the army, nor is it so competent to judge of the needs of the medical department as it otherwise might be. It would seem, however, that it should be disposed to accept the earnest recommendations of those who are best informed and most capable of judging of those needs. He must, indeed, be obtuse who has not learned what these needs are; and, in the event of failure to grant the relief so earnestly sought and so palpably required, a heavy responsibility will rest on those who have shut their eyes and ears to the facts and who have opposed this beneficent legislation.

DISREPUTABLE ADVERTISERS AND THE MAILS.

When all other sources fail to check disreputable medical advertisers, the U. S. postal laws frequently intervene most efficiently. A postal inspector who had already done good work in Boston was recently ordered by the Postmaster-General to go to New York to investigate a certain class of advertisers in the newspapers of that city. He found many advertisements which showed their intent clearly and that the advertisers were illegally using the United States mails; the counsel of the County Medical Society was able to furnish what amounted in some instances to legal proof of the offense against the United States laws. A large number of the more prominent of these advertisers were called to account, and it is said that many of them will be compelled to leave their present fields of activity and to seek other locations—some of them, perhaps, under pretty rigid physical restrictions. A similar campaign could successfully be carried on in every large city, and it is a pity that the United States laws will not cover a wider field and take in the accomplices who print and publish these advertisements, as well as those that actually use the mails. We can hardly pick up a newspaper published in our large cities that does not contain some advertisements whose criminal intent is easily discerned. The publishers of these papers use the mails, as well as the advertisers, and in some extreme cases have also been reached by the United States laws. Here, as elsewhere, however, a little sinning is tolerated or overlooked.

INTERRUPTION OF CIRCULATION AS A THERAPEUTIC MEASURE.

There are a number of subacute or subchronic hyperplastic processes, especially involving the joints, that do not yield readily to ordinary therapeutic measures. For these Dr. William Ewart¹ has proposed a plan of treatment that, in his hands, has yielded encouraging results. The procedure has the merit of simplicity, requires no special apparatus, and has the added advantage of freedom from danger under proper conditions. The part to be treated must first be rendered anemic; the patient assumes the recumbent posture,

and the part is elevated and squeezed free of blood. An Esmarch tourniquet or a length of rubber tubing of suitable thickness is then applied. The tubing may be tightened around the member in single or in double loop over a slight protecting pad. The tube can either be drawn tight, the ends being held, or it may be coiled over itself to any degree of tightness. The constriction may be maintained for from 30 seconds to three minutes, in accordance with the nature of the conditions present in the individual case, and should be released suddenly at the conclusion of the treatment, the member having previously been lowered to the dependent position. The procedure is not applicable to inflamed or tender nerve trunks, nor to senile and calcified arteries. The application of the ligature is followed by pallor of the part, with emptying of the superficial veins, and a subjective sensation of pressure. Later numbness appears, passing into anesthesia. Pain and tenderness lessen and may even disappear, and there may be a feeling of recovery of some degree of power for active movement. The removal of the ligature is followed, after a varying interval, by a visible, bright blush of the skin and nails and a sense of increased heat. The treatment has been applied to the following conditions: Subacute, subpyrexial synovitis, persistent or relapsing, in young subjects of rheumatic tendency; deforming, soft, puffy, nodular arthritis in women, with chronic, quiet, intra-articular and periarticular effusions and thickenings, and the late massive arthritic thickenings, with articular rigidity or with much stiffness. In view of the results reported and of the apparent harmlessness of the measure, it is entitled to fair and extensive trial. The method of treatment described is suggestive of that proposed and practiced by Bier. From this, however, it differs in the production of a primary anemia followed by a secondary arterial hyperemia. It is not improbable, on the other hand, that the good effects observed after the employment of both forms of procedure are, in reality, due to identical conditions.

THE FLY AND THE TUBERCLE BACILLUS.

The recent stress which has been laid on alimentary infection in tuberculosis should lead to a more careful consideration of the means by which tubercle bacilli may reach the alimentary canal. The recent studies of Lord¹ show that the ubiquitous fly may play an important part in alimentary transmission. The bacilli not only pass the alimentary canal of the fly unchanged, but undergo a marked proliferation there. Fly specks may contain as many as 5,000 bacilli, and, according to Lord's computations, thirty infected flies may deposit within three days from 6,000,000 to 10,000,000 tubercle bacilli. The danger does not seem to be from the liberation of tubercle bacilli in the air, but from the deposition of the fly specks on food. That this can and does occur under certain circumstances was abundantly demonstrated by our experience with typhoid fever during the Spanish-American war. We should bear in mind the possibility of infection by the fly and be much more

strict than we are at present in the disposition of sputum and in the protection of food stuffs, and this refers particularly to the summer months.

WHO PAYS THE BILLS?

A rather expensive and attractive reprint of an article that appeared in a St. Louis drug journal, entitled "A Legislative Scheme of the American Medical Association, a Conspiracy to Establish a Physicians' Trust," is being widely circulated. From the number of copies that have been sent us, with the envelopes in which they were originally mailed, we should imagine that it is being circulated to every newspaper in the country, and, of course, to all medical journals. According to a correspondent in Georgia, it is also being distributed through the mails by certain congressmen under their "franking" privilege. This is certainly an interesting development! The article itself, as will readily be appreciated by those who read it and who know the actual facts, is made up of misrepresentations and specious arguments. The animus that prompted the article is, of course, evident to those who know what the *National Druggist* represents. Evidently, the object in circulating this reprint in the manner above outlined is to create an antagonism toward the medical profession, because of its efforts in favor of the Pure Food Bill and of legislation against frauds in medicines. The question arises, "Who is paying for this?" for it is certainly costing some one considerable money, even if the free use of the mails is secured by some congressmen. Is it to be imagined that this St. Louis drug journal supplies the money? Are the individuals who are sending out their reprints attacking the Association and its work, with their "arguments" for the use of preservatives in foods, etc., paying their own printing and postage bills? Is it not extremely likely that those who are feeling the influence of the Association in its fight against nostrums have something to do with this attempt to disparage the medical profession, and especially the American Medical Association, in the eyes of the public? We have evidence that "patent medicine" men are mailing these pamphlets from Chicago; but they are also being mailed from other cities. At least one nostrum manufacturer, who has made a fortune out of our profession, is directly connected with the scheme.

Medical News

ILLINOIS.

Hospital Dedicated.—The Memorial Methodist Hospital, Mattoon, was formally dedicated and opened to the public, March 15.

Hospital Corps for Third Infantry.—Lieut. Robert C. Bourland, assistant surgeon, Third Infantry, U. S. A., Rockford, is organizing a hospital corps for that regiment.

Hospital for Oak Park.—A hospital to cost \$100,000 is to be erected at the northeast corner of Wisconsin Avenue and Monroe Street, Oak Park, for the Sisters of Misericordia.

Physicians Acquitted.—Drs. Harry B. Vanatta, Lerna, and P. M. Little, Jonesville, charged with manslaughter, were acquitted in the Ellington County Circuit Court, March 22.

St. Francis Hospital to Have New Building.—The increasing demands on St. Francis Hospital, Evanston, have necessitated the erection of a new building, which will have a frontage of 216 feet, will be five stories in height, will be equipped with all modern appliances and will cost \$100,000.

New Medical Association.—Physicians and dentists of Waukegan and North Chicago met March 12 and organized the Waukegan Medical Association, with the following officers: President, Dr. Edward F. Gavin; vice-president, Dr. Jacob F. Roemer; secretary, Dr. Beatrice Pearce; treasurer, Dr. William S. Bellows, all of Waukegan, and executive committee, Drs. Leon H. Tombaugh and Charles E. Daniels, Waukegan, and Dr. Fuller, North Chicago.

Chicago.

A Narrow Escape.—Firemen and policemen saved the lives of the four children of Dr. William G. Willard, March 17, when his house caught fire and filled with smoke, preventing the escape of the children from their rooms.

Donation to Library.—Dr. Nicholas Senn has presented to the Newberry Library the working library of Professor Meissner on internal medicine and a botanical library of between 200 and 300 volumes, consisting mainly of old and classic works on herbs.

Buys Site for Hospital.—John P. Wilson has bid in, at judicial sale for about \$80,000 practically, the entire block of ground bounded by Fullerton and Lincoln Avenues and Orchard Street. The property is to be the site of the new Maurice Porter Hospital.

Personal.—Dr. Eugene S. Talbot has been unanimously elected an honorary member of the Stomatological Society of Hungary. —Dr. and Mrs. A. F. Henning have returned after nine months in Europe. —Dr. Edward G. Burman was overcome by gas while searching for a leak under his house, March 22, and is seriously ill.

Tuberculosis Institute Incorporated.—The Chicago Tuberculosis Institute was incorporated March 19 by Dr. Arnold C. Klebs, Dr. Henry B. Favill and Edward B. Bicknell. The organization will rent a building, establish a free dispensary, collect statistics and carry on an active educational campaign. Dr. Frank Billings is president of the institute, and Dr. Henry B. Favill, chairman of the board of trustees.

Fined and Imprisoned.—Dr. N. News Wood of Christian Hospital notoriety was sentenced to imprisonment for ten days in the county jail and to pay a fine of \$100 for contempt of court, March 23. The offense consisted in the violation of an injunction obtained by Dr. John B. Murphy in December, 1904, restraining the defendants from using his name or photograph in their literature. The Christian Hospital was also fined \$250.

Mortality for the Week.—There were 533 deaths reported during the week ended March 24, equivalent to an annual death rate of 13.55 per 1,000. This compares favorably with the death rate of the preceding week, 14.10, and with that of the corresponding week of 1905, which was 15.21. Pneumonia still heads the list with 97 deaths; consumption caused 73 deaths; heart diseases, 52; acute intestinal diseases, 32; nervous diseases, 30; nephritis, 25, and violence including suicide, 21. The death rate for pneumonia is especially low as compared with last year, but there was an increase in the mortality from typhoid fever which it is hoped is only temporary, as the water supply of the city is apparently free from suspicion at present.

LOUISIANA.

At a meeting of the St. James Parish Medical Society, held Dec. 7, 1905, the following resolutions, offered by Dr. B. A. Colomb, were adopted:

We hereby protest against the practice of certain life insurance companies in paying less than five dollars for any medical examination. We see no reason why a smaller fee should be paid for one examination than for another since the work is always the same. We can not further understand why some life insurance companies have been able to maintain a minimum examination fee of five dollars while others have not.

We have noted with surprise that, while the examination fees were being cut down on the plea of economy, all other expenses were enormously increased, although the examining physician is the most important employé of any company, as its success or failure will depend on the quality of his work.

We demand that the Louisiana State Medical Society take some action on this question at its next meeting, and that it be brought before the American Medical Association in proper form.

MARYLAND.

Hospital Incorporation.—The Emergency Hospital of Easton was incorporated March 19. A site will be procured and a building erected in the near future.

Jury Could Not Agree; Case Retried.—In the case of "Dr." J. Tompkins and F. William Horman, a druggist of Hagerstown, charged with being responsible for the death of Miss Jean Maxwell, who died as the result of a criminal operation, the jury disagreed and the defendants were released under bonds of \$10,000. The retrial was to be held March 20.

Want New Hospital.—A delegation from Somerset County appeared before the finance and ways and means committees of the legislature, March 13, asking for an appropriation of \$10,000 to build a general and marine hospital at Crisfield and \$2,500 a year for its maintenance.

Would Tax Professional Men.—Delegate Luckey of Frederick County has introduced a bill into the legislature authorizing the mayor and aldermen of Frederick to tax practitioners of law, medicine, surgery, dentistry and veterinary surgery in that city, and to impose a license tax on all lawyers, physicians, surgeons, dentists and veterinary surgeons in Frederick, and to require all such persons practicing in Frederick to procure a license.

Legislative Doings.—The bill amending the medical practice act, which was introduced into the house of delegates early in the session, was unfavorably reported by the hygienic committee, March 22. A delegation of Baltimore physicians appeared before the committee against it on that day. The amendment was designed to let in without examination all those practicing medicine up to June, 1906.—It is said the joint committee of the two houses of the legislature have prepared their report of appropriations and the same is published, from which it appears that the Johns Hopkins Hospital has been cut out entirely. The Johns Hopkins University receives \$50,000, and the University of Maryland (for University Hospital), \$600,000.—The governor has signed the bill passed by the legislature relating to vital statistics which has been mentioned in THE JOURNAL.

Baltimore.

Respiratory Diseases.—Pneumonia continues to lead in the causes of mortality, 39 deaths being attributed to it last week. Other similar diseases causing mortality were: Influenza, 7; bronchitis, 5, and whooping cough, 2.

Lectures.—Dr. Joseph Gichner of the tuberculosis commission, lectured on tuberculosis at the Relay public school, and talks on the same subject were made at the same time by Drs. William Royal Stokes and William K. Fareckson.—Dr. Hiram Woods delivered a lecture by request before the Davis Medical Society of Jefferson Medical College on "Ophthalmia Neonatorum."

Personal.—Dr. Thomas Shearer will spend the summer in Europe.—Dr. Eugene Lee Crutchfield, who recently was operated on at St. Joseph's Hospital, is now convalescent.—Drs. John W. Chambers and Thomas S. Latimer have both been ill, but are reported as improving.—Dr. George Heller was thrown out of his carriage in a runaway, March 24, and badly lacerated about the head and face.—Dr. John A. Tompkins has been appointed resident physician at Warm Springs, Va.

MASSACHUSETTS.

Communicable Diseases.—There were reported to the State Board of Health in February, 411 cases of scarlet fever, 581 cases of diphtheria, 3,018 cases of measles, 80 cases of typhoid fever, and 19 cases of cerebrospinal meningitis.

Nervous Derangements.—Dr. James Jackson Putnam, professor of neurology at Harvard University Medical School, has attracted very large audiences to the series of popular lectures on "Certain Prevalent Nervous Derangements and the Outlook for Their Prevention," which he has been giving at the Lowell Institute.

Hospital for Incurable Consumptives.—In supporting an appeal for an appropriation of \$150,000 to establish a hospital for incurable consumptives, ex-Representative Gogins offered to give the state a site of 53 acres in Walpole, about 20 miles from Boston. There are said to be 14,000 incurable tuberculous patients in Massachusetts.

Impure Food Convictions.—The State Board of Health continues to push adulteration investigations and secured in January, 25 convictions for the sale of impure milk, butter, lard, gluten, maple syrup, catsup, hamburger steak, lamb's tongues, sausages, malt liquors, early chlorata, corn daze, extractum glycyrrhizæ, extractum zingiberis fluidum, oleum olive, spiritus camphoræ and tinctura iodi. Three hundred and thirty-seven dairies were inspected, in 104 of which no fault was found.

No Medical Legislation.—There seems little likelihood of any important medical legislation by Massachusetts this year. The committees have reported against osteopathic registration, the restriction of the practice of medicine and even the definition of what shall constitute "a practitioner of medicine," asked for by the State Board of Registration. Antivivisection, however, has received a quietus for another year. The petition for protection of articles of food from contamination meets with little favor.

MINNESOTA.

Abortionist Sentenced.—Dr. Theron H. Bly, Minneapolis, has been sentenced to imprisonment for three and one-half years in the state penitentiary for performing a criminal operation.

Hospital Burned.—The Bray Hospital, Biwabik, was totally destroyed by fire, February 25, the inmates and patients narrowly escaping with their lives. The loss is estimated at \$15,000, with insurance of \$6,000.

Hospital Notes.—A contract has been let for the construction of the Evangelical Lutheran Hospital at Mankato. The building is to cost about \$35,000.—A sanitarium is to be erected at Mounds Park, Dayton's Bluffs, St. Paul, to cost about \$76,000. The Warren Hospital has been completed and is now in active operation.

Ask for Malchow's Pardon.—The medical men of Hennepin County and the faculty of Hamline University are taking up the cause of Prof. C. M. Malchow, sentenced to imprisonment for a year for violation of the United States law by sending an obscene book through the mails, and within a few days a petition will be presented to the President, asking that Dr. Malchow be pardoned.

Verdict Against Physician Set Aside.—In the case of Anna Moore against Dr. Cornelius Williams, St. Paul, for \$20,000 damages for an operation alleged to have been performed on the right ear of the plaintiff when the left ear was the one affected, in which the jury found a verdict for the plaintiff of \$14,322.50, and at a second trial a verdict for \$3,500, the district court has set aside the verdict and has ordered judgment entered in favor of the defendant.

Personal.—Dr. Windfield S. Laton, Minneapolis, has sailed from Honolulu for China.—Dr. Frederick A. Dunsmoor and daughters, Minneapolis, have sailed from Liverpool on the *Carnarvon*.—Dr. Henry C. Stuhr and wife, Argyle, sailed for Europe, March 15.—Dr. Harry E. Burdette, St. Paul, was picked up on the street, February 15, and is seriously ill.—Dr. Frederick E. Walker, Worthington, has gone to Hot Springs, S. D., where he will take charge of the surgical department of the Sisters' Hospital.

Banquets.—Dr. Burton J. Merrill, Stillwater, gave a banquet to the Washington County Medical Association, March 13, at which a number of physicians from St. Paul and Minneapolis were present. Dr. Thomas C. Clark officiated as toastmaster.—Dr. John Charles Adams, Lake City, was tendered a banquet, March 10, by the Wabasha County Medical Society, of which he had been a member for many years, on the occasion of his seventy-fifth birthday. Dr. William F. Wilson officiated as toastmaster, and in behalf of the association Dr. Emery H. Bailey presented to Dr. Adams a gold-headed cane suitably inscribed.

MISSISSIPPI.

Personal.—Dr. Samuel A. Gassaway, New Albany, is seriously ill with pneumonia.—Dr. William R. McKinley, Columbus, has resigned as a member of the State Board of Health and Dr. Robert S. Curry, Columbus, has been appointed to the position.

State Laboratory Needed.—A bill has been introduced in the lower house authorizing the establishment of a pathologic and chemical laboratory for the State Board of Health, appropriating \$2,500 for its establishment and providing for its self-sustenance by a fixed fee table.

Dr. Hunter Fined.—Dr. John F. Hunter, Jackson, was fined \$200 January 26, at New Albany, for contempt of court, the offense of which he was adjudged guilty being his non-appearance as a witness against Dr. R. A. Holcombe, Hickory Flat, who was indicted for practicing medicine without a license.

Cost of Yellow Fever.—Dr. John F. Hunter, Jackson, secretary of the State Board of Health, has submitted a supplementary report to the legislature on the yellow fever of last summer and the expense of the fight to control it. The disease made its appearance in 15 different localities and there were 837 cases, with 61 deaths. The total expense incurred on this account was \$13,220.28.

Uniform Quarantine Recommended.—The State Board of Health in a supplementary report to the legislature regarding the yellow-fever epidemic of last year, advises a uniform quarantine system for the entire state. It recommends that a sufficient appropriation be made by the legislature to the State Board of Health to provide for carrying out such a system. It also provides a heavy penalty against practitioners in the state who willfully fail to report contagious and infectious

diseases to the State Board of Health. It requests also the establishment of a bureau of vital and mortuary statistics and that the secretary of the State Board of Health should be paid a salary sufficient to enable him to devote his entire time to the health interests of the state.

Warren County Meeting.—At a recent meeting of the Warren County Medical Society the following officers were elected: President, Dr. John A. K. Birchett; vice-president, Dr. John P. O'Leary; secretary, Dr. Sydney W. Johnston; treasurer, Dr. B. I. Hicks; censor, Dr. Hollie B. Wilson, and delegate to the state association, Dr. Hugh H. Haralson, all of Vicksburg. The society adopted the following resolutions:

Resolved, That it is the sense of the Warren County Medical Society that the legislature of the state of Mississippi should pass a law requiring every proprietary or patent medicine or food for the sick offered for sale in the state of Mississippi to have its formula printed in plain English on its label, and where any drug usually considered poisonous enters into the formula, then the word *POISON* in prominent letters also be inscribed thereon. It is further

Resolved, That each member of this society should make it his business to urge our representatives in the legislature to do all in their power to have such a law passed.

WHEREAS, The Public Health and Marine-Hospital Service was fit to station Dr. G. M. Gulteras in charge of the yellow fever epidemic at Vicksburg; and

WHEREAS, Dr. Gulteras so ably and successfully controlled the situation by his high executive and professional ability; demonstrating so conclusively that he was eminently fitted to fill this position; therefore, be it

Resolved: 1. That we, the members of the Warren County Medical Association, tender thanks to the president of the United States and to Dr. Wyman, surgeon-general, U. S. S., for so considering the interests of the people of Vicksburg by sending to us Dr. Gulteras; and 2. That we extend our thanks to Dr. Gulteras for his generous treatment of the members of this association and for his faithful services; and 3. That the secretary be instructed to mail a copy of these resolutions to President Roosevelt, Dr. Wyman, Dr. Gulteras, and that the same be published in the *Mississippi State Medical Journal*, *The Journal of the American Medical Association*, and the local newspapers.

MONTANA.

Laboratory Installed.—A bacteriologic laboratory has been installed in St. Ann's Hospital, Anaconda, which will be at the service of the physicians of the city.

January Deaths.—Dr. Thomas D. Tuttle, Helena, secretary of the State Board of Health, reports that during January there were 266 deaths in the state, equivalent to an annual death rate of less than 9 per 1,000.

Declared to be Murray's Property.—In the suit of Dr. Isadore D. Freund against Dr. Thomas J. Murray, both of Butte, in which the plaintiff claimed that he had certain rights in the business of the Murray Hospital in which he was a partner for twelve years, the restraining order was denied and the petition for an order to show cause was dismissed, March 9.

Society Election.—The Silver Bow County Medical Society held its annual meeting in Butte, March 15, and elected the following officers: Dr. R. C. Monahan, president; Dr. Frederick W. McCrimmon, vice-president; Dr. Grace W. Cahoon, secretary; Dr. Creswell T. Pigot, treasurer; Drs. John Donovan, Thomas J. Sullivan, E. F. Maginn, John W. Scanlan and R. C. Monahan, trustees, and Dr. Donald Campbell, delegate to the state association, all of Butte. The society gave a banquet at the Thornton House, Butte, March 7, in honor of Dr. Robert L. Gillespie, formerly of Butte, but now of Portland, Ore.

NEW JERSEY.

Camden Health Report.—The report of the Camden board of health for February shows that only 28 cases of contagious disease were reported, as follows: Scarlet fever, 14; diphtheria, 6; typhoid fever 5, and tuberculosis, 3.

New Seashore Hospital at Atlantic City.—The board of governors of the Atlantic City Hospital announced, March 19, that a new hospital building is soon to be erected at a cost of \$100,000. Subscriptions amounting to \$50,000 have already been made.

Train and Ferryboat Fumigated.—The Camden board of health, having been notified by the officials of the Atlantic City Railroad, March 20, that a train at Kaighn's Point terminal had on board a child ill with diphtheria, the train was immediately placed on a side track, and the train and ferryboat fumigated.

Personal.—Dr. Charles C. Phillips, Deerfield, who has practiced medicine in that place for 52 years, has retired and will remove to Pitman.—Dr. Harris Underwood, Woodbury, has been appointed to the house staff of Cooper Hospital, Camden.—Dr. O. A. Clark, Long Branch City, was chosen president of the Baltimore Medical Alumni Association.—Dr. James

Hoffman has been appointed health commissioner of Jersey City, vice Dr. Gordon K. Dickinson, resigned.—Drs. Samuel E. Ewing, Leesburg, and George Spence, Vineland, are ill with diphtheria.

Oppose Osteopathic Bill.—The West Jersey Homeopathic Medical Society, at its regular quarterly meeting held in Camden, February 21, discussed the proposed osteopathic bill which is to come up before the present session of the legislature. The society had already previously condemned the passage of the bill. It was the consensus of opinion of the society that if osteopaths practice in the state they should comply with the requirements now in force, viz., a certain standard of preliminary education, a four years' course in a medical college, and examination in the fundamental sciences of medicine. The members all pledged their influence to uphold the present standard of requirements, which though high, treats all applicants alike regardless of "ism" or "pathy."

NEW YORK.

Smallpox Scare.—It is reported that the smallpox situation is serious in Putnam. Many persons have been exposed.

Farm for Tuberculosis Plant.—Dr. Darlington, president of the New York board of health, has purchased a large farm at Otisville, Orange County, near the tract of land which New York City originally purchased for the establishment of a sanitarium for tuberculous patients.

Water Supply Bill Passed.—The bill permitting New York City to go into Ulster County for water has been passed. It permits the payment of direct and indirect damages to property owners as well as to mill hands who lose their work by reason of factories having to shut down.

Pollution of New York Bay.—Representatives from New York City recently held a conference with Governor Higgins to urge him to take a vigorous stand against the pollution of the waters of New York Bay by sewage deposits from New York and New Jersey. The report of Dr. Daniel Lewis, state commissioner of health, which was made several years ago, was reviewed and it was urged that a bill providing for the further investigation of this matter be passed at the present session of the legislature.

The Labeling of Colored Foods.—Attorney-General Mayer, in construing the food law, has rendered the opinion that where goods are artificially colored they must be so labeled that the constituents and character of all preservatives are clearly set forth. He holds that compounds not injurious to health may be sold under their own names, provided that they are not displayed, advertised or sold in such a manner as to deceive the public. He calls attention to the fact that the statute prohibits imitation and substitution, and also prohibits mixing and coloring substances in such a way as to conceal inferiority.

New York City.

More Spitters Caught.—Twelve spitters were arrested by a sanitary squad in Brooklyn, and each was compelled to pay a fine of \$1.

Hospital for Westchester.—As a result of a meeting held March 6 in the interest of a hospital for northern Westchester \$4,000 has already been pledged. When \$12,500 has been raised the hospital will be begun.

Jury Censures Hospital.—A coroner's jury under direction of Coroner Harburg has brought a verdict censuring the authorities of Fordham Hospital for removing a patient who was in no condition to be moved to Bellevue Hospital. The coroner declared that he was going to put a stop to the practice of making a dumping ground of Bellevue.

Dormitory for City Hospital.—Plans have been filed for a new three-story dormitory for the nurse of the City Hospital on Blackwell's Island. The building will cost \$42,000. Plans were also filed for the enlargement of the male dormitory of the city workhouse on Randall's Island by the addition of a three-story annex at a cost of \$22,000.

Garbage Disposal.—The Brooklyn Rapid Transit Company has reclaimed 200 acres of waste land in the last ten months by filling with incinerated garbage. Incinerators, in addition to burning the material put into them, create a large amount of steam power which can be utilized with profit. This company runs and heats its car shops at East New York with steam from one of its incinerators. It will soon run dynamos with steam generated at another plant.

Patent-Medicine Evils.—Fifteen hundred members of the West Side Branch of the Young Men's Christian Association adopted resolutions, after hearing Norman Hargood of *Collier's Weekly* talk on the evils of patent medicines, petitioning the

senate and assembly to pass the bill known as the Stevens-Wainwright bill for the proper labeling of medicinal preparations containing alcohol or narcotic or other potent drugs so as to show the presence and percentage of such ingredients.

Physicians Must Pay Physicians.—The suit of Dr. Thomas E. Satterthwaite to recover from the estate of the late Dr. Egbert Guernsey \$450 for professional services was tried on March 23 before Justice McCarthy and a jury in the City Court. The jury returned a verdict for the plaintiff for the full amount. The right of one physician to charge another was discussed, and the chief point brought out by the testimony of a number of physicians was that specialists consider it right, and that it is customary to charge other members of the profession.

"Magic Boot" Man Held.—A manufacturer of "magic boots" for cripples, Matthew Hilgert, was held on trial for grand larceny on March 18. Hilgert's special manager was held for practicing medicine without a license. The defendants were arrested at the instance of the County Medical Society. At the hearing the court room was lined with cripples who had appeared to testify that they had paid prices ranging as high as \$1,500 for a pair of magic boots. Some of the cripples declared that their cases had become hopeless since using the shoes. Hilgert was held in \$1,000 bail and Whitehouse in \$500.

A New Milk Ordinance.—In order to prevent milk from spoiling, preservatives of various kinds have been employed with increasing frequency. Sometimes the milk has been sterilized, and some large dealers have taken it on themselves to pasteurize their milk. The health department wishes to be sure that the milk comes into the city absolutely pure and sweet, and as many dealers are installing pasteurizing plants the following ordinance has been submitted: "No milk which has been heated, pasteurized, sterilized or subjected to heat in any manner, with the purpose of preservation, shall be received, prepared, held or kept for sale or delivered in the city of New York, unless it bears a label stating plainly the process to which the milk has been subjected."

Try to Find Work for the Handicapped.—At the monthly conference of local charity workers, held under the auspices of the Charity Organization Society, the topic discussed was how to find employment for the physically and socially handicapped so as to render them self-supporting. Dr. Theodore C. Jane-way told of the large number of patients who, when discharged from the hospitals, would live many years if they could only change their employment and secure lighter work. There were many deaths among laboring men due to diseases of the heart, but it was almost impossible to get these people to change their work. A large number of discharged tuberculosis patients relapsed because they insisted on returning to their old environments and employments. These persons should be sent to the country to work.

Subway Conditions.—Trials have been made with the vacuum cleaning process in the subway, and this process seemed to remove the greasy dirt easily and quickly from the girders as well as from the tiling and woodwork. It has not been decided as yet whether this method of cleaning will be adopted or not. Dr. George A. Soner reported the results of his investigations of subway conditions during the past six months to the Academy of Medicine on March 15. From a large number of analyses he concluded that the air was not deficient in oxygen, differed very little from the air of the street in the quantity of carbon dioxide and contained only about one-half as many bacteria as the air of the streets. Some of the unpleasant odors were due to oils used on machinery, disinfectants used in the toilets and the slate used in the roadbed, which emits a peculiar odor when wet. He considered that the only menace to health was the lack of proper care in regard to cleanliness of the stations, toilets, roadbeds near the stations, etc. He recommended certain regulations as to methods of cleaning and a rigid enforcement of the law regarding sniffing. The dangers were only those due to overcrowding in other localities.

OKLAHOMA.

Destroyed by Fire.—The house of Dr. John E. Standifer, Cheyenne, was entirely destroyed by fire, February 27. The loss was \$2,200, with \$1,700 insurance.

Smallpox.—Five cases of smallpox are reported near Cement, Caddo County, and three cases at Keebi. Several district schools have been closed and quarantine is being rigidly enforced.

Sanitarium Report. The report of the Oklahoma Sanitarium for the Insane for the month of February showed 489 patients at the institution, an increase of about 20 over the previous month.

Fined for Operating Hospital in City.—Dr. W. M. Turner, Lawton, was recently arrested for maintaining a hospital within the residence portion of the city for private gain, and fined \$25 and costs.

Personal.—Dr. John Threadgill, Oklahoma City, has been appointed a member of the board of regents of the territorial normal schools.—Dr. J. K. Julian, Covington, has been appointed coroner of Garfield County, vice Dr. John J. Barber, Hunter, resigned.

New Hospitals.—Dr. Joseph B. Rolater has opened a new private hospital with accommodation for about 25 patients at Oklahoma City.—Lawton Sanitarium has been incorporated with a capital of \$10,000 by Drs. Charles S. Meridith, James L. Lewis, W. M. Turner, David A. Myers, Lewis T. Gooch, Edwin D. Meeker and Alexander N. Campbell.

Medical Societies.—The Kingfisher County Medical Society at its annual meeting elected Dr. Joseph A. Overstreet, Kingfisher, president; Dr. Charles O. Gose, Hennessey, vice-president, and Dr. Charles W. Fisk, Kingfisher, secretary and treasurer.—Southwestern Oklahoma Medical Society was organized in Hobart recently by physicians of Greer, Washita, Custer and Kiowa counties. The following officers were elected: Dr. W. L. York, Hobart, president; Dr. Alfred H. Bungardt, Cordell, secretary-treasurer; Drs. A. W. Holland, Hobart, and Walter E. Hempstead, Arapahoe, vice-presidents; and Drs. T. J. Dodson, Mangum; W. J. Curley, Cordell; W. W. Miller, Gotebo; William Tidball, Barton; Walter E. Hempstead, Arapahoe, and James M. Bonham, Hobart, censors.

OREGON.

New Building Completed.—The new building for the medical department of the Willamette University, Salem, is now practically completed and ready for occupancy.

Law Is Mandatory.—The attorney-general has decided that the law requiring each county to establish a county board of health and to appoint a physician as secretary of the board, is mandatory.

Non-payment of Occupation Taxes.—Warrants for the arrest of nearly 100 physicians and lawyers, who, it is alleged, have failed to pay the occupation tax, were issued in Portland, February 15.

Insane from Drugs.—Dr. Donald C. Lazier, Condon, has been adjudged insane and committed to the Oregon State Insane Asylum, Salem. His case is one of mental aberration due to the use of opium and cocaine.

Personal.—Dr. Charles J. Smith, Pendleton, has been elected president; Dr. Edward A. Pierce, Salem, vice-president, and Dr. Robert C. Yennev, Portland, secretary, of the State Board of Health.—Dr. James P. Wallace, Albany, has been elected mayor of the city.—Dr. Eugene Du Cas, Roseburg, has been forced temporarily to suspend practice on account of ill health.

New Hospitals.—New Providence Hospital, West Roseburg, is now under construction and will be completed during the year.—A new Catholic hospital is to be established in Albany in the residence of a former priest at that place, to be conducted by the Sisters of Mercy.—A new general hospital has been opened at Grant's Pass, with accommodations for 16 patients.

PENNSYLVANIA.

Disastrous Fire.—The house of Dr. Lucius A. Warren, Lancaster, was destroyed by fire March 13, the family narrowly escaping with their lives. The loss is total, as no insurance was carried.

Sent to the Penitentiary.—"Dr." Edwin Hooper was sentenced, March 24, to 15 months in the penitentiary after two convictions for conspiracy to perform a criminal operation on a young woman of Johnstown, who died four years ago as a result of the operation.

Anniversaries.—The Neweastle Medical Society celebrated its semi-centennial March 7.—In honor of the twenty-fifth anniversary of his entrance into medical practice, Dr. John T. Howell was given a banquet by his associates and the staff of the Wilkes-Barre Hospital. Dr. Howell was also presented with a pearl-stick-pin.

Personal.—Dr. Willoughby H. Reed, Norristown, sailed for Jamaica, March 1.—Dr. Thomas P. Cole has been elected president of the council of Greensburg.—Dr. Edward L. Davis has been elected vice-president of the Berwick board of health, and Dr. Alexander B. McRea has resigned as a member of the board.—Dr. George M. Brubaker has been appointed health officer of Mercersburg.—Dr. Mase S. Davis, Pittsburg, returned March 7 after four months abroad.—Dr. John K. Far-

rar, Audenreid, has gone to his home in Newburgh, N. Y., to recuperate from the effects of a recent accident.—Dr. E. Justin Butler, Wilkes-Barre, was operated on for appendicitis, March 19.—Dr. George Hemminger has been elected president, and Dr. Samuel L. Diven, secretary, of the medical staff of Carlisle Hospital.

Philadelphia.

Bacteriologic Laboratory Report.—The report of the bacteriologic laboratory of the health bureau for February shows that 1,180 diphtheria cultures were examined and that 2,951,500 units of antitoxin were supplied.

Violation of Pure Food Laws.—Three dealers were held for court, March 22, charged with violating one of the recently enacted pure food laws in not labeling grains. The defendants were held in \$500 bail for each charge against them.

Bequests.—The following bequests have been approved by the Orphans' Court in the distribution of the estate of Charles Hart: Children's Seaside Home for Invalids, Sanitarium Association, Philadelphia Home for Incurables and Children's Hospital, \$5,917.40 each.

To Relieve Hospital Overflow.—The finance committee of councils, on March 22, at a special meeting, appropriated \$45,000 to fit up additional quarters in the Philadelphia Museums building to relieve the overcrowded condition in the Philadelphia Hospital.

Emergency Corps Disbanded.—Director Potter of the department of public safety has issued an order calling in the badges distributed among the members of the medical emergency corps organized during the previous administration, on the ground that there is no further need for the services of the corps.

Patients at Widener Home.—More than 200 patients have applied for admission to the Widener Home, although only 100 can be accommodated. The first examination was made on March 22. No children will be received except those crippled by disease and those who can be benefited or cured. The age limits for admission are 4 and 10 years.

Suits to Remedy Eyesight Defects.—The committee on elementary schools, together with Captain Thorton of the compulsory education department, having been obliged to exclude from school a great many children on account of defects of eyesight which the parents refused to have remedied, on March 21 decided to bring suit against parents who persist in their refusal.

Organizing a Northwest Branch.—A number of physicians residing west of old York road and north of Hunting Parkway convened March 15 to organize the Northwest Branch of the Philadelphia County Medical Society. The requisite number of signatures was obtained to a petition for a new branch. Dr. Morris J. Karpeles was chosen temporary chairman, and Dr. Howard D. Geisler, temporary clerk.

Dixon Scores Quacks.—Dr. Samuel G. Dixon, state health commissioner, at a meeting of the college physicians, in discussing Champe S. Andrews' paper on quackery, March 19, advocated revoking the state medical license of the "quack" doctor the moment it was proved that the man was carrying on a business in such a manner as to bring disgrace on the medical profession and harm to the victim of his charlatanism. He suggested the preparation of a bill empowering the state medical board to revoke licenses in certain contingencies.

Health Report.—The total number of deaths reported for the week ended March 24 numbered 586. This is a decrease of 5 from the number reported last week and an increase of 55 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 27; pertussis, 3; consumption, 60; apoplexy, 22; acute respiratory disease, 122; enteritis, 25; appendicitis, 7; Bright's disease, 56; marasmus, 4; measles, 18; diphtheria, 7; cancer, 13; heart disease, 50; suicides, 3, and accidents, 10. There were 332 cases of contagious disease, with 34 deaths, as compared with 448 cases and 48 deaths reported in the preceding week.

Personal.—Dr. Montgomery Biggs, chief resident physician of Philadelphia Hospital, has resigned.—Drs. Ralph O. Clock, Thomas McDonnell and Robert Payne resigned from the resident staff of St. Agnes' Hospital, March 21.—Dr. Carl Vischer is ill at his home with nervous prostration.—Dr. John Marshall, professor of chemistry in the university, sustained a fracture of the leg in a fall, March 23.—Dr. Edward E. Montgomery, who has been confined to his home with bronchial pneumonia, has completely recovered.—Dr. Theodore Fassitt and wife sailed for Genoa, March 24.—Dr. Walter J. Cathall has been committed to the Philadelphia Hospital for the insane.

Food Preservation by Chemicals.—Dr. Harvey W. Wiley, head of the government chemistry bureau, made an address at the Philadelphia College of Pharmacy, March 20. He said that the use of chemicals in the preservation of foods is not only harmful, but unnecessary. "Manufacturers only use formaldehyde, etc., because this method is cheaper than sterilization or freezing. Food need not be impure, and I insist that if a manufacturer doctors his wares he should be compelled to admit the fact by the use of a proper label." Dr. Wiley then showed that the accumulative effect of preserved foods was harmful.

Home Treatment of Tuberculosis.—Dr. Thomas H. Mays, medical director of the Philadelphia Clinic for the Home Treatment of Consumption Among the Poor, announces the appointment of a staff of physicians consisting of Drs. John D. McLean, Ralph H. Spangler, J. P. Bethel, Andrew D. Carter and Arthur C. Wolf. Daily clinics will be held between 3 and 4 every afternoon excepting Sunday, for the treatment of chest troubles in patients who are able to walk. Those who are unable to walk and are not under medical care will be visited by physicians and nurses, if necessary, on giving notice at the clinic rooms. The medical service and nurses are free, but a nominal charge for medicine is made to those who are able to pay.

SOUTH CAROLINA.

Personal.—Dr. Francis L. Frost, health officer of Charleston, has resigned and Dr. Henry W. De Saussure has been appointed temporarily to the position, pending election.—Dr. C. Fred Williams, city physician of Columbia, was operated on for appendicitis at the Columbia Hospital, February 25, and is doing well.

New Hospitals.—The new building of the Columbia Hospital has been completed and is in active operation.—The formal opening of Roper Hospital, Charleston, occurred February 19. The new hospital is on the site of the former city hospital and is under the charge of the South Carolina Medical Association, which agrees to care for the pauper and emergency sick and injured of the city in consideration of an annual payment of \$28,000.

Unlicensed Practitioners Convicted.—The Greenville County Medical Association scored the first victory in its campaign against illegal practitioners January 29, when "Dr." C. P. Price was convicted of the unlawful practice of medicine. The prisoner is said to have fled the country. The law provides for a fine of not less than \$50 nor more than \$500, or imprisonment of not less than thirty nor more than ninety days, or both, at the discretion of the trial judge.

Examiners' Fees for Life Insurance.—As the result of the recent action of the Equitable Life Insurance Company in reducing its fee for examinations from \$5 to \$3, the Kershaw County Medical Society, at a called meeting in Lugoff, February 26, adopted the following resolution:

Resolved, That we revert to our previous fee for life insurance examinations, \$5.00 for old-line companies, that pay the fee, and \$3.00 for fraternal assessment companies where the applicant pays the fee, and that the secretary be requested to notify all the Societies in the state and its officers of the state medical association, requesting them to uphold us in this matter.

Tristate Medical Association of Virginia and the Carolinas.—The eighth annual session of this association was held February 27 and 28 at White Stone Lithia Springs, S. C. A large attendance of the leading medical men of the three component states were present and a program of unusual attractiveness was given. The great number of excellent papers provoked so much discussion as to practically preclude the reading, save by title, of fully one-half of the papers presented. It is predicted a three days' session will become a necessity another year. The following officers were elected: President, Dr. Rolfe E. Hughes, Laurens, S. C.; vice-presidents, Drs. Isaac M. Taylor, Morganton, N. C.; Wilson E. Driver, Norfolk, Va., and James A. Haynes, Blackstock, S. C., and secretary-treasurer, Dr. J. Howell Wax, Waynesville, N. C. The next session will be held in Norfolk, Va., in 1907, the date to be fixed by the executive committee.

TENNESSEE.

Election of Officers.—At the annual meeting of the Memphis and Shelby County Medical Society, March 6, the following officers were elected: President, Dr. James L. Barton; vice-president, Dr. Cummings Harris; and secretary, Dr. J. Wesley Price.

Personal.—Dr. John R. Rathnell, Chattanooga, has been appointed to succeed the late Dr. Edward A. Cobleigh as a member of the state anatomical commission.—Dr. William A. Shafer, Chattanooga, has been re-elected a member of the board of public safety.

Staff of City Hospital. The mayor of Memphis has appointed Dr. James L. Andrews to the department of medicine; Dr. Frank D. Smythe to the department of gynecology; Dr. Max Henning to succeed Dr. John M. Maury in the department of surgery; Dr. Edward C. Elliott to the department of ophthalmology, and Dr. Alexander Erskine to the department of obstetrics in the City Hospital.

Refuse Low Schedule of Medical Fees.—At the meeting of the Memphis and Shelby County Medical Society, March 6, the following motion was adopted:

Motion.—That the acceptance of the absurdly low schedule of medical fees as proposed by the Maryland Casualty Company is derogatory to the dignity of the profession and that no member of this society should accept the same; also, the proposal of such a schedule of fees by this company is an insult to the medical profession.

Patent Medicines and Counter Prescribers.—The Memphis and Shelby County Medical Society, at its meeting March 20, adopted resolutions unqualifiedly condemning the action of certain druggists in assisting to defraud the public by means of guaranteeing cures by patent medicines, condemning the practice of counter prescribing by druggists, and notifying the druggists of the city that should they persist in these practices they will gain the antagonism of the members of the society.

Rutherford County Medical Society.—At its meeting in Murfreesboro, March 7, the society appointed a committee on public health and legislation, consisting of Drs. Enoch H. Jones, Murfreesboro; William E. Yuhce, Readyville, and Harry C. Rees, Murfreesboro. The delegate to the state medical association was instructed to vote for transactions in book form and not for a state journal. The president appointed a committee composed of Drs. Enoch H. Jones, William C. Bilbro and Rufus Pitts, all of Murfreesboro, to prepare for the coming of the organizer of the American Medical Association, Dr. J. N. McCormack, Bowling Green, Ky., who delivered an address at Citizens' Theater, March 13.

TEXAS.

Fire Loss.—Fire in Amarillo, March 11, destroyed the offices of Dr. John W. Pearson, with a loss of about \$4,500, on which there was no insurance.

District Association Meeting.—The Fifth District Medical Association at its meeting at Seguin, March 9, elected Dr. W. A. King, San Antonio, president; Dr. John T. Fitzsimons, Castroville, vice-president, and Dr. R. L. Knolle, Seguin, treasurer.

College Wants Railroad Hospital.—Fort Worth Medical College has made a proposition to the chief surgeon of the Missouri, Kansas & Texas Railroad to add accommodation for 50 patients to the hospital department, provided the road will make use of the building as its hospital in Texas.

Must Not Advertise.—At its last meeting the Tarrant County Medical Association decided henceforth to oppose all forms of advertising by physicians in daily papers, hotel registers and the like; with the exception that when a physician moves his office, he is allowed to advertise the fact for ten days; that when a newcomer locates, he may advertise for ten days; and that a practitioner who has been away from town for two weeks or more is allowed to advertise his return for the same length of time.—The Fort Worth Medical Society, at its meeting, March 7, adopted similar resolutions.

Insurance Examination Fees.—The Hopkins County Medical Society, at its meeting, March 12, adopted the following resolutions relating to fees for examination for accident and indemnity insurance associations:

Resolved, That all fraternal or assessment insurance companies or societies shall pay not less than \$3 for each medical examination, and extra for additional work or secondary examinations of urine, etc.

Resolved, That all old line insurance companies shall pay a minimum fee of \$5 for each medical examination, and further,

Resolved, That we, as members of the Hopkins County Medical Society will not report on any accident for indemnity or sick benefit for any company or society that does not regard the moral character of its risks.

Practice of Medicine Bills.—The Smith County Medical Society at its meeting, March 13, approved, with modifications, the bill to regulate the practice of medicine in Texas, which prescribed more stringent regulation, more strict qualifications, more rigid examinations and a compulsory examination for practitioners from outside the state. It also approved the anatomic bill proposed by the state medical association, which permits medical colleges in the state to obtain bodies of paupers and unclaimed persons for anatomic material.—At a called meeting of the Galveston County Medical Society, March

16, the medical bill was discussed and approved, with amendments. The bill contemplates a state medical board to be made up of representatives from the regular, homeopathic and eclectic schools, and the osteopaths, the representation being apportioned according to the number of practitioners of each school in the state. The state board is to be the examining board, and all practitioners must be examined before this board before being granted license to practice medicine.

Personal.—Dr. V. E. H. Reed, Holland, suffered amputation of a finger on his right hand on March 3, on account of septicemia.—Dr. Pierre M. Kuykendall, Mooly, was stricken with cerebral hemorrhage, February 28, and is critically ill.—Dr. E. Brazier Blalock, Woodlawn, has announced his candidacy for the Democratic nomination for lieutenant governor, one plank in his platform being that he will protect the people of Texas from medical quacks and incompetent practitioners.—State Health Officer Tabor is expected to return from Europe in time to attend the meeting of the state health officers of the gulf states, April 2.—Dr. William E. York, Giddings, was seriously injured about the head and shoulders in a runaway accident, March 14.—Dr. Richard H. Harrison, Bryan, has resigned as mayor, to take effect April 1.—Drs. Orlando Patton, Midway, and A. H. Spear, Madisonville, have been appointed inspectors for the United States Public Health and Marine-Hospital Service at Port Limon, Central America, and Colon, Panama, respectively, to inspect the sanitary condition of the cities and their methods of disinfection, etc.

UTAH.

Personal.—Dr. Edward A. Rich, Brigham City, has sailed for Germany.—Dr. Samuel G. Paul has been appointed assistant health commissioner of Salt Lake City.

Hospital's Debt Cleared.—Bishop Spaulding of the Episcopal diocese of Utah has succeeded in raising money to clear off the debt of \$40,000, which had been carried by St. Mark's Hospital for several years.

Medicine Hawkers Licensed.—The city council of Logan on March 7 passed a new license ordinance whereby medicine hawkers are required to pay a license of \$35 a month instead of \$3 per day as before.

Merger.—The *Utah Medical Journal* has been absorbed by the *Denver Medical Times*, which is now to be known as the *Denver Medical Times and the Utah Medical Journal*. The Utah edition will be prepared by local editors, of whom Dr. W. Brown Ewing is chief and Dr. Franklin H. Raley, associate.

County Society Takes Action.—The Salt Lake Medical Society, at its meeting March 13, extended its congratulations to the senators from Utah for their vote for the Pure Food bill and thanked them for their support.—At the meeting of the society, February 18, resolutions were adopted condemning the acquittal of Dr. E. S. Payne, charged with performing a criminal operation on Miss Alice Ferguson, who died from its effects.

WASHINGTON.

New Buildings Opened.—The two new ward buildings at the Western Washington Hospital for the Insane, Port Stellanoom, have been completed and turned over to the board of control.

Personal.—Dr. Burt Thomas has been elected health officer of Walla Walla, vice Dr. J. W. Ingram, resigned.—Dr. W. James Howells has returned from Europe and resumed practice in Spokane.—Dr. Wilson Johnston has been elected president, and Dr. Robert J. Skaffe, secretary, of the Colfax Doctors' Club.

Vital Statistics.—The births in Spokane for 1905 were 1,101, or 418 more than the reported deaths.—Walla Walla reports in 1905 only 27 cases of communicable disease, distributed as follows: Diphtheria, 19; scarlet fever, 4; measles, 3, and smallpox, 1.—Chehalis, with only 26 deaths during the year, equivalent to about 6 per 1,000 of population, claims to be the healthiest city in Washington.

Unlicensed Practitioners Fined.—"Dr." Benjamin E. Hays, an optician, of Tacoma, charged with practicing medicine without a license, pleaded guilty, and was fined \$75.—Walter Reed, of Portland, Ore., arrested in Colfax, charged with practicing medicine without a license, paid the costs of the action, amounting to about \$25, and the case was dismissed on his promise to drop the title of doctor and to use the title of optician or refractionist.

WEST VIRGINIA.

Fire Damage.—In a fire at St. Albans, which caused a loss of \$900,000, the offices of Drs. William A. Heslop and Delaford Herford, and the residence of Dr. John H. Suntherland, were destroyed.

Personal.—Dr. Gus Capito, Charleston, sailed from New York for Germany, March 10.—Dr. John W. Ramsey, Clarksburg, is seriously ill.—Dr. J. E. McDonald, Logan, is in the Kessler Hospital, Huntington, seriously ill with typhoid fever.—Dr. Thomas F. Downing, superintendent of McKendree Hospital, has resigned, to take effect March 15.

Society Meetings.—The Fayette County Medical Society held its annual meeting at Thurmond, January 26, at which Dr. W. W. Hume, Quinnimont, was elected president; Dr. Lancy B. Rupert, Nuttallburg, vice-president; Dr. John W. Hopkins, Fayetteville, treasurer (re-elected), and Dr. Charles F. Mahood, Oakhill, secretary (re-elected).—The Ohio County Medical Association held its annual banquet in Wheeling, January 31. Dr. Samuel L. Jepson, Wheeling, presided as toastmaster.

WISCONSIN.

New Buildings for Sanitarium.—Dr. Richard Dewey, superintendent of the Milwaukee Sanitarium, announces that the two new buildings for the institution, namely, a fireproof ten-room hospital for psychopathic cases, with special provision for hydrotherapeutic treatment, and a convalescent cottage with twelve rooms arranged in suites, will be ready for occupancy April 1 and May 1, respectively.

Oppose Contract Work.—The physicians of Racine as a body, including practitioners of all schools, have pledged themselves not to take any more contract work, insurance, lodge or otherwise, during this year. The opposition raised by certain lodges, factories and insurance companies has now subsided, as the local press has made it clear to the public that the people will be the gainers by doing away with medical contracts.

Supreme Court Decides Against Student.—In the case of Robert A. Burg, a dental student, against the Dental Department of the Milwaukee Medical College, in which he asked a mandamus to compel the institution to grant him a diploma, the Supreme Court reversed the decision of the lower court and quashed the writ of mandamus. The college authorities claimed that the plaintiff was notified of the ruling of the State Board of Examiners that the custom of allowing entrance requirements to be completed during the first year had been abrogated, and that students deficient in entrance requirements were required to make them up before the close of the first semester.

Personal.—Dr. W. A. Gordon, Jr., Oshkosh, has been appointed assistant surgeon of the Wisconsin National Guard, with the rank of first lieutenant, and has been assigned to the Second Infantry.—At the meeting of the Brown County Medical Association in De Pere, March 15, Dr. Prec. N. Brett, Green Bay, was elected delegate to the state medical society, and Dr. Alphonse M. Kersten, De Pere, censor.—Dr. Charles Schoenfeld, LaCrosse, sailed for Europe, March 28.—Dr. Albert P. Minshall, Viroqua, was seriously burned in the face and wrists by the explosion of a furnace in his house, February 27.—Dr. Louis Fuldner, Milwaukee, and Dr. Moses J. White, Wauwatosa, have returned after a two weeks' trip to Cuba.—Dr. Oscar Loehr, Milwaukee, has returned after a six months' visit in Europe.

GENERAL.

Medico-Psychological Association Meeting.—The sixty-second annual meeting of the American Medico-Psychological Association will be held in Boston, June 12 to 15, 1906. The chairman of the committee of arrangements is Dr. George T. Tuttle, Waverly, Mass. The secretary of the association is Dr. Charles W. Pilgrim, Poughkeepsie, N. Y.

Health Report of the Isthmus for February.—In his report of the health conditions on the Isthmus during February, Colonel Gorgas states that still another month has passed without a case of yellow fever, and that the Canal Zone is equally free from other quarantinable diseases. Among the 23,000 employees, on an average 472 were in hospital daily; a sick rate of 20 per mille. He believes that this is an excellent showing. During the month there were 56 deaths. Of these 7 were white and 49 were negroes. There were only 11 deaths from pneumonia. The sanitary work was carried on as usual.

FOREIGN.

Calendars as an Advertising Medium for Nostrums.—The governor of Minden, one of the German states, has ordered the various local authorities to pay particular attention to the advertising of nostrums, etc., on calendars and in pamphlets, and to prosecute in case they conflict with the regulations.

Jubilee of the Turkish Imperial Society of Medicine.—The jubilee meeting of this society was held during the first week in March.

The Soldiers' Teeth.—The British war office has announced that an additional dental surgeon is required for duty with troops in the United Kingdom from April 1 next. He will be required to devote his entire time to military duty and will receive a salary of £365 (\$1,825) per annum, and traveling expenses.

Pathologic Laboratory for the Women's Hospital in Melbourne.—At a recent meeting the hospital committee of the Women's Hospital of Melbourne, Australia, took under consideration the advisability of establishing a laboratory under the charge of a competent pathologist who would be required to attend the hospital on all operating days and at such other times as might be necessary.

To Feed Indigent School Children.—A bill has been introduced into the English house of commons, having for its object the feeding of poor school children. The bill met with a favorable reception at the hands of the minister for education. The principle of the bill will probably be embodied in the new education bill and the only remaining question is the source from which the money is to be drawn.

In Memory of Semmelweis.—The Medical Club of Budapest has voted to have an artistic tall drinking vessel made as a memorial to Semmelweis, to be used only on great occasions, when the "pokal" will be handed around with great ceremony. It will be used first at a banquet to the memory of Semmelweis, on his anniversary, and in the following years, only when some important medical or scientific question is to be discussed or tribute paid to some departed notability.

Out-Patients and Fees.—In order to check to some extent the abuse of the out-patient departments of the large London hospitals, it has been suggested that a small fee be charged each out-patient after the first visit. This suggestion, however, did not meet the approval of the members of the council of the Metropolitan Hospital Sunday Fund, who were of the opinion that any abuse that may already exist could be effectually met by an efficient system of investigation conducted by a competent staff engaged in visiting the homes of the patients.

Clinic Sued for Damages from Carelessness of Nurse.—A nurse at the University Clinic at Bonn gave a caustic powder by mistake to a patient who had entered the clinic for an operation the next day. The action of the caustic caused injuries which still persist to a certain extent, and the patient sued the university for \$3,000. The university claimed that it was a state institution and not individually responsible, but the local and supreme courts decided that the university was legally responsible for injury resulting from carelessness in its clinic and sustained the claim for damages.

Juvenile Smoking Bill.—A bill has just been introduced into the British parliament designed to carry out the unanimous recommendation of the physical deterioration bill: 1. To prohibit the sale of tobacco and cigarettes to children below a certain age; 2. to prohibit the sale of tobacco and cigarettes in candy or other shops frequented by children. The operative clause would enact that any person selling, giving or supplying tobacco in any form to or for the use of any person under the age of 16 would be liable to a fine on first conviction not exceeding \$5 and on further conviction not exceeding \$10.

The Organized Profession in Germany.—The semi-official societies that insure against sickness (Krankenkassen), of the city of Münster recently refused to grant the request of their medical officers for increased remuneration and introduction of "free choice" of physicians by patients. It was one of a few places where the old rates still prevailed. The medical officers resigned in a body, and the companies tried to attract outsiders to take their places. They were unable to procure enough medical attendants for their sick policy-holders, and the municipal authorities promptly interfered and closed a contract with the former medical officers on the latter's terms.

Protection of Nurses.—For some time the view has been gaining ground in Great Britain that nurses should be registered. Nursing calls for special skill, technical ability and a thorough training. The public, of course, is no judge of the qualifications, and in consequence the calling is greatly abused. Many women who pose as trained nurses are impostors and in some instances moral delinquents against whom protection is necessary. There can be no doubt but that registration would be of benefit to the public as well as to genuine nurses. A deputation holding these views recently waited on the president of the privy council, requesting that steps be taken to provide legislation to meet the case. The minister, without

binding himself to any definite promise, held out hopes that the government would consider the matter, and that ere long the registration of nurses would be secured.

Sixth International Congress of Applied Chemistry.—One of the eleven sections of this congress, which will be held at Rome, April 26, is to be devoted to medicine. The medical section is in charge of Prof. E. Paterno of Rome. It is to be divided into subsections for medical hygiene and chemistry, pharmaceutical chemistry and bromatology or the science of alimentation. The five preceding congresses were held at Vienna, Berlin and twice at Paris since the first congress at Brussels in 1894. The Italian state railroads and navigation companies allow a reduction of 40 or 60 per cent. to members of the congress.

A New Morgue for Sidney.—It is reported that Sidney, Australia, is at last to have a new morgue. The *Australasian Medical Gazette* states that ever since the South Sidney morgue was destroyed because the site was required for the new railway station, the only available morgue has been the old North Sidney morgue, and that the building is not only ridiculously inadequate, but that it is also out of date as an institution for the important medicolegal work which must be done there. Plans have been prepared for the erection of a coroner's court-house and offices and a morgue, but only the latter is to be completed at present.

Dentists for Public Schools.—The city of Ulm, Germany, has decided to install a school dentist, who will examine and treat the children's teeth as occasion demands, giving up private practice. Investigation showed that only 2 per cent. of all the boys in the high schools and none in the primary schools had ever had their teeth examined by a dentist. Among the girls the findings were more favorable, over 36 per cent. in the high schools and a few in the primary schools having been examined. Fillings were found in from 3.3 to 16 per cent. The question as to what proportion of the dental work shall be done free of charge is not yet decided. The experiment of school dentistry has proved successful at Strassburg. It is said that only 160 children with sound teeth were found among 2,103 between the ages of 6 and 8, while the number was only twice this in a corresponding number of children between 3 and 6. Headache, earache, stomacheache, as well as toothache, have nearly vanished from the schools since this system of compulsory dentistry was established.

Inspection Under the New Aliens Act.—The new aliens act which came into force in England in January has already had the effect of excluding many "undesirables." Since this act has been law immigration to Great Britain has been greatly curtailed, a significant feature being that scarcely one case of trachoma has been seen among immigrants in London. The act, too, has had the result of drawing attention to the disgraceful way in which some of the immigrants are brought to London. Dr. H. Williams, medical officer of health for the port of London, recently gave extracts from the report of the sanitary authorities with regard to the accommodation provided for aliens on some ships. One ship in particular, which came from St. Petersburg, carrying 305 alien steerage passengers, was in a filthy and offensive condition. The available air space per capita was only 60 cubic feet and floor space 8 square feet. No provision was made for the separation of the sexes. Ventilation and lighting were unsatisfactory, provisions insufficient, and in the event of bad weather the passengers had to be confined to the quarters, as the after-deck was wholly occupied by horses.

Abortionists' Advertising in Spain and Belgium.—At a recent session of the Spanish Senate, Dr. A. Pulido, now prime minister, formerly chief of the National Sanitary Service, and one of the editors of the *Siglo Medico*, called the attention of the legislators to a crime which he said is being committed constantly in the most cynical and scandalous manner. As an instance of the class of crimes to which he referred, he read an advertisement from a daily paper as follows: "Menstruation appears after taking three times the Dr. Paris prescription, whatever may be the cause of its suppression. In short," he continued, "the crime is that of abortion, against which four special laws have been enacted. This crime is practiced with such frequency that if it were possible to ascertain the number of victims, society would be horrified. I am certain that I am not exaggerating when I state that there are persons who have committed this crime forty, fifty and up to sixty times. There is no way to prosecute them, when such advertisements as this are allowed to be published in the papers. The daily press publishes them without giving thought to their contents; they are merely one among a certain number of ads. The penalties provided

evidently do not fit the case, as such advertisements are constantly recurring, some of them announcing hours for consultation at which what is left unsaid in the advertisements is realized." He called on the highest authorities in the cabinet to take up the matter officially, and it was formally referred to them. His address is given in full in the *British Medical Journal* for March 3, 1906.

Relief for London Hospitals.—A new proposal has been made for relieving the expenditure in London hospitals. Mr. Sidney Holland, secretary of the London Hospital, in Whitechapel, explains that much of the burden is due to the great expense of modern surgery, and to the lower middle classes having neither money nor the house room for serious operations. Many people who could afford to pay a certain sum can not bear the expense of going to a satisfactory nursing home and are compelled to enter a hospital when they need surgical care. Mr. Holland proposes that a large hospital be built where accommodation may be obtained, either expensive or cheap, but where the patient is to deal directly with his surgeon on a professional and not on a charitable footing. The argument is made that the carrying out of such a plan would free the charity hospitals from liabilities which do not rightly belong to them, and at the same time give many people a real alternative to charitable treatment. It must be borne in mind that unlike the hospitals of America, nearly all hospitals in Great Britain are free, and that only a few admit paying patients. There are in London itself only two hospitals in which are private wards; of these St. Thomas' is the best known. The really serious criticism which has been raised with regard to the scheme has to do with the financial arrangement. It is doubted whether the best surgeons would feel inclined to meet the proposal by a reduction of their fees in proportion to the purse of the patient with a limited amount of money to spare. It has been suggested that a public meeting should be called to consider the proposal either in the city of London or in the city of Westminster.

Passive Resistance in Lower Austria.—Representatives of all the medical organizations in lower Austria held a mass meeting at Vienna, March 3, to manifest their sympathy with the united stand recently taken by the country practitioners in protest against the absurdly low remuneration allowed by the national authorities for certain medical duties. The organized stand taken by the profession in Austria was mentioned recently in these columns, page 736. At the mass meeting funds were raised and the representatives of the various medical councils pledged their influence to insure the organized backing of the profession at large. Appeals have been made to the central authorities on behalf of the physicians by the various communities, several uniting in a petition which comments appreciatively on the fact that the physicians have held high the standard of humanity during their dispute with the authorities, not stinting their services to the sick, the poor or to the communities at large. Their "passive resistance" merely affected certain of their functions, and although their procedure caused the state officials and the district boards of hygiene a vast amount of trouble, yet suffering humanity was not affected by it. The plan of "passive resistance" is merely to report to the authorities every case of suspicious disease, without stating the diagnosis, as "suspicion of sepsis or diphtheria" or "suspicion of scarlet fever or measles." The district board is compelled by law to send the district physician to every case of infectious disease in which the attending physician is not sure as to the diagnosis. The petition further states that the efforts of the physicians in question (the "Gemeindeärzten") have the deepest sympathy of the subscribing communities. They appeal to the central authorities to hasten to put an end to the present unbearable condition of the physicians by revising the present laws on the subject to harmonize with the frequently expressed wishes of the medical profession, and to inform the medical profession of this intention so that the passive resistance may be brought to an end before the country loses all its country practitioners. The *Leininger Verband* of Germany has given \$5,000 to help the cause and our Vienna exchanges comment on this gift as not only a generous and welcome material aid, but as inserting a leaf of gold in the history of the medical profession. It adds that a brilliant example is given to all the members of the profession by this act of medical solidarity.

LONDON LETTER.

The Institute of Medical Sciences.

The project of the University of London to centralize the preliminary teaching of medical students, which is now carried

out, often under difficulties at the various hospitals, is progressing. The university has decided to establish, as soon as funds are available, a school of preliminary medical science, including anatomy and physiology, at South Kensington. Toward the building fund the Goldsmiths Company has given the sum of \$50,000, which raises the amount now obtained to more than one-half of that required to begin building operations.

The Royal Institute of Public Health.

This institution was formed recently for the purpose of instructing all persons interested in the subject of public health. It consists of a library, museum and laboratories. Arrangements are made for the delivery of a series of lectures by well-known authorities. A number of mayors and the principal officials of London boroughs as well as some from outlying districts were invited to inspect the chemical and bacteriologic laboratories. These laboratories were instituted about a year ago with the view of enabling physicians and others (such as sanitary inspectors) desirous of securing a public-health qualification to receive suitable training, and also as a place where municipal authorities and others would have the opportunity of obtaining reliable chemical and bacteriologic reports and advice. So far, the advantages of the laboratories have been sought to a considerable extent, and it was with a view to make their utility better known that this inspection took place. A number of experiments by which adulteration is detected were shown also, and an address on the objects of the institute was delivered by Prof. W. R. Smith, the president.

The Administrative Control of Phthisis.

The local government board of Scotland has issued an important circular which is the first official statement that local authorities have serious responsibilities and powers in regard to the control of pulmonary tuberculosis. As the disease is recognized as infectious, it is pointed out that the provisions of the public health act regarding infectious diseases apply to it. These include the arrangement of proper premises and apparatus, and attendance for the disinfection of bed clothing, etc., and the disinfection of rooms or houses, with powers of entry, when necessary, to disinfect and to destroy infected articles. When patients with phthisis are treated at home the board recommends that the local authorities insist on the disinfection of the house at frequent intervals. The importance of thorough disinfection is emphasized and it is insisted that it should not be left to the friends of the patient or fellow-workmen, but should be carried out by skilled officers. Disinfection is also recommended in connection with all places of public resort (schools, churches, halls, theaters, markets, railway stations and public conveyances). Special attention is directed to the suppression of spitting and the disinfection of sputum. Local authorities are assured that they have power to prevent infected persons from exposing themselves in streets or public places without proper precautions against spreading the disease. The establishment of tuberculosis dispensaries, hospitals for early cases (sanatoriums), reception houses or hospitals for patients in an advanced or dying condition, and colonies and homes for convalescent patients able to work but requiring medical supervision, are sanctioned.

The Purity of Potable Spirits.

Largely because of its persistent advocacy by the *Lancet*, a most important reform has been introduced in regard to the purity of potable spirits. For years brandy and whisky have been sold mixed with cheaper spirits of other kinds and no question was ever raised as to adulteration. In 1902, in a report of a special commission on brandy, the *Lancet* expressed the hope that the chemical analysis of spirits would be conducted with greater attention to detail than had been given to it by public analysis. Numerous prosecutions were then instituted against persons who sold under the name of brandy concoctions containing cheap spirits made from grain and other substances, and convictions were obtained. Attention was then directed to whisky. The health authorities of the borough of Islington have just prosecuted vendors for selling, in one case Scotch and in the other case Irish whisky, which contained a large percentage of patent-still (otherwise silent or neutral) spirit. The case was very protracted and an enormous amount of evidence was given on both sides. The witnesses comprised physicians, chemists, distillers and various trade representatives. The analyst for the prosecution fixed as the result of examination of a great number of genuine whiskies the minimum coefficient of secondary products at 380 parts per 100,000 of absolute alcohol. In the disputed example of Scotch whisky the coefficient was 110.5 and in that of Irish whisky 174.5. The inference was that each sample consisted

of patent-still, silent or neutral spirit. This agreed with evidence of a witness called for the defense who supplied the spirit. He stated that the sample was practically young patent spirit with a "dash" of pot-still malt spirit. In the opinion of the judge, spirit produced in a patent still from a mash consisting to a large extent of maize to which a "dash" of true whisky made from barley malt in a pot still had been added is not whisky. Notwithstanding that much evidence was given to show that the public preferred a blend made in this way to true whisky the defendants were convicted. The sale of such a spirit is not illegal, but it must not be termed whisky; its nature must be stated on the label.

Vagrancy and Disease.

The departmental committee on vagrancy has just issued a valuable report which deals exhaustively with the whole subject. It includes a historical survey of the attempts to deal with vagrants from 1495 to the present day. At the periods of trade depression there are in England and Wales from 70,000 to 80,000 vagrants, and in good times as many as 30,000. Like many other of our methods of government, the mode of treating vagrants is inconsistent and illogical. "Between the poor law and the police the vagrant has flourished. The police treat him as a criminal, but do not punish him, and the poor law authorities treat him as a pauper, but do not relieve him." It is now decided that vagrants are to be handed over to the police authorities. The bona-fide seeker after work will be helped to find occupation and each police station will become an office of information as to the work of the district. On the other hand, the professional tramp will be sent to a labor colony for six months or even three years in order that he may learn to work and be cured of his habit of vagrancy. The tramp has long been recognized as a spreader of infectious disease. Dr. Armstrong, health officer of Newcastle-on-Tyne, has shown the great part played by tramps in the diffusion of smallpox. In 1893 smallpox was first introduced by vagrants into 58 per cent. of 63 large towns and was carried sooner or later into 72 per cent. on an average about five times to each town. In this way the disease was taken to 30 workhouses and to 70 common lodging houses. The dissemination of the disease was mainly due to tramps suffering from it in the modified form. In the workhouse the bath and the disinfection of clothing are a protection against the conveyance of disease by the tramp, but many more tramps come from common lodging houses where these protections do not exist. The report endorses Dr. Armstrong's suggestion that by laws should be adopted for common lodging houses, and that they should be watched by sanitary inspectors. Another interesting point in the report is the dietary for casual wards and labor colonies. In investigating this subject valuable assistance has been received from Professor Foster and Dr. Hopkins of Cambridge. Guided by them, the committee has taken 70 gm. of proteid and 3,000 calories as the standard of diet for the casual wards and labor colonies. This reduced standard is due to the results of the recent investigations of Professor Chittenden and others. A considerable economy will be effected by adopting this standard. It is calculated that the diet need cost only 40 cents a week. Under the old standard the cost was \$1 or \$1.25.

Action Against Physician for Conveying Scarlet Fever to a Puerperal Woman.

A remarkable case has just been decided in the courts which, in consequence of its widespread importance to the profession, has attracted much attention. A physician was called to a case of scarlet fever, after seeing which he went home and disinfected his hands. Two hours later he was summoned to a case of labor. On the fifth day the woman developed scarlet fever. The woman's husband alleged that the doctor conveyed the disease to her and claimed damages for negligence. For the plaintiff it was urged that a puerperal woman was specially liable to infection with scarlet fever in a specially malignant form and that more complete precautions against conveying infection should have been taken. Counsel supported this view by reading extracts from the writings of Dr. Galabin and Dr. Boxall, but as he did not call these authorities, the judge ruled that this was not evidence. On the other hand, Drs. Herman and Hunter were called for the defense and stated that a puerperal woman is neither more nor less liable to scarlet fever than other people; that puerperal scarlet fever is rare and that it is not more dangerous than scarlet fever apart from the puerperal state. The next point in the plaintiff's case was in support of the writings of Dr. Boxall, who stated that the following precautions should be taken after visiting a case of scarlet fever before going to a case of labor: "1. A disinfect-

ant bath; the whole body should be immersed, the head above all, for the hair is a veritable network to entangle the poison; 2. a complete change of clothing; 3. active outdoor exercise." The physician, according to his evidence, after seeing the case of scarlet fever, walked home, a distance which occupied about five minutes. He found a message to go to the case of labor. He disinfected his hands and arms with izar and changed his coat. He visited another patient, walking about a quarter of a mile, and took a cab and drove a distance of two and one-half miles to the patient's house. He went in and shook hands with her. Then he retired to an ante-room, took off his coat, scrubbed his hands and arms with soap and water and repeated the process in a solution of corrosive sublimate, and finally rinsed them in a solution of izar. After putting on rubber sleeves, which he had previously disinfected, he examined the woman. Two physicians were called for the plaintiff and stated that a physician should transfer a case of labor to another if he was called to attend it within two hours of visiting an infectious case. This would be their own course. They considered that in order to disinfect himself a physician should change all his clothes and take a bath. For the defendant a large amount of medical evidence was called, including Dr. Herman (London Hospital), Dr. Hunter (London Fever Hospital), and Professor Spencer (University College Hospital). They all agreed that the precautions taken were the ordinary ones and quite sufficient, though there were more complete ones, such as those described, but that these were impracticable in general practice. None of these witnesses agreed with the opinions quoted from Dr. Boxall of the special susceptibility of the parturient woman to scarlet fever. The jury gave a verdict for the plaintiff.

Medical Legislation

New York Practice of Medicine.

The position taken by the Educational Department of New York state regarding osteopathy is shown in the following extract from a communication sent to the members of the legislature by Mr. H. J. Rogers, first assistant commissioner of education: In our opinion the state should not recognize any school of practice in medicine any more than any special creed or cult. Medicine is so rapidly developing into an exact science and depends so completely on the latest discoveries in biology and kindred sciences that the only logical position which it seems to us the state can assume concerning those who are to practice the healing art in any form on their fellow-men is that they shall, first, receive a thorough preliminary education; second, a thorough professional education—the requirements of both to be fixed by the state; third, to be licensed to practice medicine. They will be thus fitted and left free to choose any form of practice which may appeal to their judgment.

The Medical Society of Erie County has also sent a protest against the osteopathic bill to every assemblyman and senator in the state. The society denounces the bill as a pernicious measure, believing that its passage would lead to evils so great as to be criminal in character. It recognizes that the main object of the bill is to legalize the practice of the thousands of osteopaths now practicing in New York rather than to provide for the education of others in the future. The bill is also considered objectionable because it provides for a multiplication of examining boards and for three separate standards or requirements for the practice of osteopathy.

Blister Sign of Death. Dr. Ott of Lillebonne has found the "explosive blister" a valuable means by which to distinguish between real and apparent death. He has simplified Marteno's technic and has found the test practicable and reliable. The forearm is drawn out horizontally, allowing sufficient space between it and the ground for a candle. The flame of the candle or of a taper or match is then held beneath it, allowing the flame to touch the skin on the anterior aspect of the forearm. In a few seconds an air blister forms and bursts, but there is no fluid. If the person is still alive, an ordinary blister including serum forms instead of the dry, explosive-gas blister. *Gaz. Med. Belg.*, Feb. 22.

Correspondence

Pauper Fees by Wealthy Corporations.

MARYLAND CASUALTY COMPANY,
Office of the President.

BALTIMORE, March 10, 1906.

To the Editor:—Your issue of March 3 contains a letter from Dr. C. H. Emery regarding the schedule of fees this company is paying physicians for immediate surgical attention to injured persons for whom we agree, under our policies, to obtain such service. You have appended to Dr. Emery's letter certain comments. The letter and the comments are of such a nature that they may possibly work some injury to this company, if allowed to go without reply. You will, of course, as a fair journalist, give to this reply equal prominence to that which you gave to Dr. Emery's letter and your own comments.

I am at a loss to understand why a matter of this kind should be thought by any one a proper subject for newspaper publication. It is purely a matter of agreement or disagreement between two parties. If one of the parties (the company, for instance) finds that the other party (the doctor) does not see his way clear to work at the fees offered, it would be a foolish and unbusiness like proceeding to rush into print with a tirade against the doctor as an extortioner. And it is equally so for the doctor and the editor to indulge in heroics because they think the fees offered are too small. If the time and skill of Dr. Emery are worth, in his judgement, taking all the features of the question into account, more than the company offers, he has an unquestioned right to decline the offer. If another doctor believes it is to his advantage to accept the offer, all things considered (although probably he would be entitled under ordinary circumstances to larger fees), it would be a piece of impertinence for any one to criticise him for doing so. The attitude of the good Dr. Emery and of your esteemed editorial self is in its essence the attitude of the trade unionist and walking delegate who assume to say that no man shall work for a figure other than is fixed by "the union." It is un-American and unreasonable.

This is the way the matter is viewed by the very large number of doctors who have agreed to the fee schedule which your good friend, Dr. Emery, and yourself criticise so unmercifully.

JNO. T. STONE, President.

[We are glad to give Mr. Stone's letter a place in our columns, as it is a fair example of the policy of insolence and greed governing many of those holding high positions in the insurance world in their dealings with medical men. It is strange, however, that our correspondent can not understand why he and his company are not left unmolested to deal as they please with the helpless individual doctor, or why an organ representing the physicians of this country should comment on the injustice which they are perpetrating on the profession and advise its readers to resent it.

It is notable that none of the deserved criticism and disgrace which insurance officials recently have brought on themselves has attached to their medical departments. Even in the home offices the medical men have been poorly compensated as compared with the lay officers, and yet, on false and specious pleas, the medical examiners have been asked to bear a disproportionately large share of the first steps in economy. Without the courtesy of a conference or the opportunity for protest, medical men who had spent years of time and much money in preparation for their duties and who had always been poorly paid, were cut 40 per cent. in their fees by a stroke of the pen.

One of these same institutions has recently employed a man as president at a salary of \$80,000 a year, who has had no training for the position, and who had been serving his country for \$8,000 a year. As his predecessor's salary had been \$100,000 a year, he at once announced that he had generously cut his own salary 20 per cent, and that other salaries in the home office would be scaled at the same rate, but the medical examiners, who appear to have had no friends at court, were to be sliced 40 per cent. At least this is what the Maryland Casualty Company has done.

In justification, the plea is made that assessment and co-operative companies and lodges, heretofore condemned as unworthy of confidence and discussion, have never paid decent fees to physicians. In the face of this record we confess that the talk about trade unions and walking delegates only make the impression on us of an impertinence.

There was a time when the medical men had no organization and hardly dared to make even a protest. It is very different now. We now have approximately 50,000 members in our county societies reaching into 2,400 of the 2,830 counties in the United States, and by concert of action can control the situation over a large part of the country.

It should not be difficult to see that cheap doctors, which usually spells "uneducated doctors," are as dangerous as insurance examiners as they are as family physicians. We therefore suggest that physicians make no reply to such communications from any source regarding cut-rate fees for their services. Proper dressings could hardly be furnished for the fees proposed in the schedule of the Maryland Casualty Company, and no self-respecting physician ought to sell his services to such a corporation at wholesale and have them retailed to the people of his own community at prices which have enabled these companies to amass a fortune and until recently to defy public opinion.

It is hardly necessary for us to say that we heartily favor legitimate insurance, both accident and life, but it is a public business and a fair subject of criticism, and Dr. Emery did both the profession and the people a service in bringing this great mistake in policy to our attention.—Ed.]

Race Suicide (Criminal Abortion).

FORT COLLINS, COLO., Feb. 24, 1906.

To the Editor:—For some time there have been many criminal abortions performed in our city, and the thought occurred to me that by getting the physicians and ministers together and formulating a statement as to the gravity of this crime we might do something to check it. A meeting was called and the statement I send you was formulated and signed by the persons whose names are appended.

The intention was to have a lot of these printed so that each physician could have a supply and distribute them where he thought they would do the most good. While we have not yet carried out this last part of our plan, I believe our action has had an excellent effect on physicians who had been doing or might be induced to do that kind of work.

E. STUVER.

STATEMENT.

Human life is the most sacred thing in the world. So deeply is this fact grounded in our very being or nature that all civilized nations have enacted stringent laws protecting human life and prescribing severe punishments for those who destroy it. In spite of these facts there is a misapprehension on the part of some and an evasion on the part of others, as to the time in the development of the human being when these legal enactments and moral obligations become operative and of binding force. Human life with all the potentialities of the fully developed human being begins just as soon as there is a vital union of the male and female generative elements, and the destruction of this life, no matter how lowly the form or early the stage of development, is just as much the destruction of a human life as it is to kill an infant, a child or an adult.

Believing it to be the duty of all intelligent and progressive men and women to do everything in their power to encourage and to promote good, to lessen evil and to transmit unimpaired to their descendants the heritage they have received from the past, we desire to call attention to one phase of the race-suicide problem which has permeated the whole fabric of our society and is causing more suffering and death than all the wars of the world put together. Operating as it does by secrecy and stealth, it is undermining the very foundations of morality and religion, and is becoming a serious menace to the health and perpetuity of the race.

We further believe that many women, who do not fully understand the gravity of the crime nor the dangers that attend its performance, suggest or insist on it themselves or allow

themselves to be persuaded to have it done by the cowardly, conscienceless criminals who do this kind of work. It is almost needless to say that we refer to criminal abortion. Abortion is the destruction or expulsion of the fetus or child at any stage, from the very beginning of its existence to the age of viability or the time when it can be born alive and survive, and every abortion deliberately produced, unless absolutely necessary to save the life of the mother, is criminal. Even in those desperate cases where such an operation is necessary, it should only be done after a careful investigation and consultation between two or more regularly licensed physicians.

All civilized nations brand this as a most serious, unnatural and revolting crime, and their laws provide for the punishment of the offenders. It is an outrage against God, man and Nature, and leaves a broad trail of death, suffering and moral degradation in its track. Every year thousands of mothers yield up their lives, victims to this dread Moloch and thousands more who do not die at once, drag out a miserable, invalid, childless existence, tortured by remorse and unavailing regrets for what has been done. Doubtless, in the darkness of the night, the forms of their murdered children rise up before their terrified souls, and like the guilty stain of Lady Macbeth, will not disappear, making their lives one long, dark tragedy unilluminated by hope.

We, the physicians and clergymen of Fort Collins, occupying as we do, positions of responsibility because of our peculiar relations with the people, feel that we are in duty bound to express ourselves on this subject.

The Climate of Egypt.

CAIRO, Egypt, March 7, 1906.

To the Editor:—One is much amused at hearing tourists', and especially invalids' criticisms of this climate. Of course, if one comes here with the idea that the sun shines continually, that the air is always dry and warm—neither too warm nor too cool—and that he or she can wear summer clothing during the day and evening, the idea will soon be dissipated.

There are cold days on which the temperature drops to 30° at times, and there are cloudy days with sometimes rain. On the whole, however, one can not growl at this climate. I find the main trouble to be that when the air is cold the indoor life is almost intolerable because there are no heating facilities. In America the houses are always very warm. Small petroleum stoves are really sufficient to make the rooms here quite cosy on the coldest days.

During the summer the days are hot, but generally the evenings are cool. In the beginning of the summer, during the American spring, we have the (Khamseens) "fifty days," in which time the hot sand storms occur. When physicians send patients to Egypt they should advise them to go to Asswan during the months of December, January and February, and to spend the other month of November or March in Cairo—or rather Helwan. Of course this arrangement is very expensive, but to send patients here and allow them to go to upper or lower Egypt as they please is harmful to the patients as well as to Egypt's reputation.

An American rheumatic patient came out this winter and at once went to Asswan, stayed a few weeks, and came back to Cairo in February, stopped at a hotel in the business part of the city, and had rooms on the ground floor looking out on the well watered garden. Of course his rheumatism was benefited!

Visitors to Cairo should be prepared to find no garden of Eden, but they can be much benefited by this beautiful farm-

ing country with the desert its near neighbor. Fresh vegetables and fresh fruits are always obtainable. The people are picturesque and can teach us patience by their "Praise God!", "If God wills!" and "Tomorrow" expressions.

The history of the ancient Egyptians, Greeks and Romans is vividly portrayed by the temples, tombs, forts, etc., and there are also the picturesque Arabic architecture and the museums, rich with the finds of Egyptologists. I add this table of the mean maximum shade temperatures of Cairo (recorded for 18 years), Alexandria (recorded for 21 years), and Asswan (recorded for 4 years). This will show how one can find the warmth and escape the heat and coolness.

	Cairo.	Alexandria.	Asswan.
January	66-64 F.	cooler	78-70 F.
February	68-71 F.	cooler	80-84 F.
March	72-78 F.	cooler	84-91 F.
April	82-86 F.	cooler	92-103 F.
May	88-94 F.	77-81 F.	hotter
June	94-96 F.	81-83 F.	hotter
July	97-98 F.	84-86 F.	hotter
August	96-97 F.	87-89 F.	hotter
September	92-88 F.	86-84 F.	hotter
October	88-84 F.	83-80 F.	hotter
November	80-73 F.	77-73 F.	hotter
December	70-67 F.	70-67 F.	82-78 F.

This shows that the climate of Cairo is not bad in March, April, October and November. Asswan is agreeable in January, February and December; and during the summer months Alexandria is quite pleasant. Of course Alexandria is not so dry as Cairo and Asswan.

J. M. KEICHLIN, M.D.

Marriages

REBA LLOYD, M.D., and Charles E. Kump, both of Bridgeton, N. J., March 22.

JAMES RUSSELL BASS, M.D., to Miss Sue Virginia Tilton, both of New Orleans, February 24.

RUSSELL B. CHACHERE, M.D., to Miss Ethel Ellen Edwards, both of Opelousas, La., March 15.

WILLIAM B. McCASKILL, M.D., Idabell, I. T., to Miss Kitty Adams of Argo, Texas, March 19.

D. P. REEDER, M.D., Paducah, Ky., to Miss Minnie Sargent of Sharp, Ky., at Cairo, Ill., March 17.

WILLIAM H. KIRC, M.D., Amory, Miss., to Miss Nellie Douglass Thomas of Memphis, Tenn., March 8.

WILLIAM TRACY BIVINGS, M.D., Atlanta, Ga., to Miss Helen Earl Randall of New York City, March 15.

TOM B. TODD, M.D., Richards, Mo., to Miss Nell Welborn of Sweet Springs, Mo., at Nevada, Mo., March 15.

LEROY R. STODDARD, M.D., New York City, to Miss Caroline E. Williams of Detroit, Mich., in New York City, March 14.

Deaths

William Turner Bacon, M.D. College of Physicians and Surgeons in the City of New York, 1871; a member of the American Medical Association, American Ophthalmological Society, Connecticut Medical Society, Hartford County Medical Society; formerly president of the Hartford Medical Society; formerly assistant in physiology in the College of Physicians and Surgeons, and curator to the Charity Hospital, New York City; ophthalmic and aural surgeon to the Hartford Hospital; consulting surgeon to St. Francis Hospital; one of the most eminent specialists in diseases of the eye and ear of New England, died at his home in Hartford, Conn., March 16, from kidney disease, after an illness of several years, aged 59.

Robert Ogden Doremus, M.D. New York University, New York City, 1851; a member of the American Medical Association; eminent as a chemist for more than 50 years; assistant to Dr. John W. Draper from 1843 to 1850; professor of chemistry and physics for many years in the College of the City of New York; a frequent contributor to the medical and scientific press; a member of the advisory commission of the department of health of New York City; since 1861 professor of chemistry in Bellevue Hospital Medical College; an expert on poisons; inventor of the system for disinfecting ships which has been in use in New York harbor for 40 years, died at his home in New York, March 22, from arteriosclerosis, after an illness of ten days, aged 81.

Frederick W. Achilles, M.D. University of Iowa, Medical Department, Iowa City, 1874; a member of the American Medical Association; formerly professor of chemistry and secretary of the faculty of the Medical College of Evansville, Ind.; a member of the Indiana State Medical Society, Ohio Valley Medical Society and Vanderburg County Medical Society; a member of the staff of the Protestant Deaconess Hospital; for many years professor of chemistry at the State University, Bloomington, Ind.; for several years assistant United States consul at Marseilles, France, died at his home in Evansville, March 18, a few hours after a fall down a long staircase at his house, aged 65.

Charles Louis Fincke, M.D. Long Island College Hospital, Brooklyn, N. Y., 1899; a member of the American Medical Association; one of the most brilliant young practitioners of Brooklyn; valedictorian of his class; clinical assistant and later associate physician in the Brooklyn Hospital; assistant to the chair of pathology in Long Island College Hospital, and secretary of the Brooklyn Pathological Society, died at his home in Brooklyn, March 19, from septicaemia, after an illness of two weeks, aged 32.

Samuel H. Freeman, M.D. Albany (N. Y.) Medical College, 1846; one of the original members of the old Albany Hospital staff, and for many years president of the board of curators of Albany Medical College; vice-president of the Albany County Medical Society, and a life member of the Medical Society of the State of New York; one of the oldest practitioners of Albany, died at his home in that city, March 15, aged 85, after a long illness.

John Powell Henry, M.D. College of Physicians and Surgeons in the City of New York, 1881; formerly health commissioner and a member of the board of health of Jersey City, N. J.; a member of the Hudson District Medical Society and the Academy of Medicine, Jersey City, died in a sanitarium near Paterson, N. J., from neurasthenia after a long illness, March 16, aged 48.

A. W. Jones, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1883; a member of the American Medical Association; formerly vice-president of the Louisiana State Medical Society and of the Morehouse Parish Medical Society; a member of the board of health of Morehouse Parish, died in Jones, La., March 16, after an illness of ten days, aged 50.

Alonzo H. Boyer, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868; for 55 years a resident of Bridgeburg, Philadelphia; assistant surgeon of the Two Hundredth Pennsylvania Volunteer Infantry in the Civil War; a member of the Medical Society of the State of Pennsylvania and of the Philadelphia County Medical Society; for many years a member of the local school board, died at his home, March 18, aged 60.

John L. Cleveland, M.D. Medical College of Ohio, Cincinnati, 1868; a member of the American Medical Association; resident physician in the Cincinnati Hospital in 1868 and 1869; for several years a lecturer and professor in the Medical College of Ohio, and a member of the attending staff of St. Mary's Hospital, died at his home in Cincinnati, March 18, from malignant disease, after an illness of two months, aged 64.

Ebenezer J. Tidd, M.D. University of Michigan, College of Medicine and Surgery, Ann Arbor, 1870, of Clarksville, Pa.; a member of the American Medical Association and one of the most prominent physicians of Mercer County; a veteran of the Civil War, died suddenly while in attendance on a patient at Transfer, Pa., March 17, from valvular heart disease, aged 61.

Rolland C. Hodges, M.D. Detroit Medical College, 1878; a fellow of the American Laryngological, Rhinological and Otolological Association; a member of the American Academy of Ophthalmology and Oto-Laryngology, State Medical Association of Texas and Houston District Medical Society; formerly of Houston, Texas, died at Del Rio, Texas, March 14.

Thomas Farrar Richardson, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1897; passed assistant surgeon in the United States Public Health and Marine-Hospital Service, of New Orleans; an expert in yellow fever, died at the New Orleans Sanitarium, March 19, from typhoid fever, after an illness of two months, aged 34.

Samuel Kent Falls, M.D. McGill University, Medical Department, Montreal, 1878; a member of the American Medical Association; from 1888 to 1892 a member of the faculty of Rush Medical College, Chicago, died suddenly in a street car in Chicago, from cerebral hemorrhage, March 22, aged 55.

Samuel J. Cooper, M.D. Memphis (Tenn.) Medical College, 1871; a Confederate veteran; a member of the Colbert County

Medical Society, and health officer of Colbert County, committed suicide by gunshot at his home in Tuscumbia, Ala., while suffering from melancholia, March 15, aged 60.

Abner C. Calvin, M.D. Jefferson Medical College, Philadelphia, 1878, of Meadville, Pa., died at the City Hospital in that city, February 24, after an illness of three days, from pulmonary edema due to injuries received in an accident in which he was thrown from his carriage, aged 51.

Taylor M. Snow, M.D. Cooper Medical College, San Francisco, 1876; a pioneer physician of Eastern Oregon; coroner of Baker County, and local physician of the Oregon Railway and Navigation Company for 20 years, died at his home in Baker City, March 6, aged 71.

Everitt Hasbrouck, M.D. New York Homeopathic Medical College and Hospital, New York City, 1865; some-time member of the State Board of Medical Examiners in New York, died at his home in Brooklyn, March 16, from nephritis, after a long illness, aged 66.

Francis Brick, M.D. Cleveland University of Medicine and Surgery, 1861; once vice-president of the Massachusetts Surgical and Gynecological Society, died at his home in Worcester, Mass., March 14, from cerebral hemorrhage, after a short illness, aged 67.

H. B. Smith, M.D. Medical College of Indiana, Indianapolis, 1885, a member of the Indiana State Medical Society and Hamilton County Medical Society, died at his home near Ohio, March 15, after an illness of several weeks, aged 59.

Dennis K. Smith, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1895, formerly of Altoona, Pa., died at his home in Colorado Springs, Colo., March 14, from tuberculosis, after a long illness, aged 40.

Brown A. Bigelow, M.D. Jefferson Medical College, Philadelphia, 1874, a member of the Medical Society of the State of Pennsylvania and the Millin County Medical Society, died March 16, at his home in Belleville, Pa., aged 44.

James Grant Gilchrist, M.D. Hahnemann Medical College or Pennsylvania, Philadelphia, 1863, professor of surgery in the College of Homeopathic Medicine of the State University of Iowa, Iowa City, died in that city, March 22.

Arthur H. Davis, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, of Philadelphia, a member of the legislature in 1890 and 1891, died in the German Hospital, Philadelphia, March 21, aged 63.

Christian B. Diebold, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1887, of New Orleans, died at his home, March 15, after an illness of three months, aged 42.

Austin M. Cowan, M.D. Eclectic Medical Institute, Cincinnati, 1852, of Valley Falls, Kan., died suddenly at the home of his son-in-law at Topeka, Kan., March 15, from heart disease, aged 77.

Nathaniel F. Hallman, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1862, died at his home in Slatington, Pa., March 18, after an illness of one week, aged 66.

C. E. Bernhardt, M.D. Kansas Medical College, Topeka, a member of the Tulare County Medical Society, died in Deer Creek, Cal., March 10, from pneumonia, after an illness of ten days.

Robert E. Lee Tadlock, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1896, died at his home in La Crosse, Ill., March 15, from typhoid fever, after a long illness, aged 38.

G. E. Sparhawk, M.D. Hahnemann Medical College, Philadelphia, 1853, died at his home in Burlington, Vt., March 14, from senile debility, after an illness of one year, aged 77.

Robert Evans Bromwell, M.D. University of Maryland, School of Medicine, Baltimore, 1850, died at his home in Fort Deposit, Md., March 21, after a protracted illness, aged 79.

Thomas L. Catherwood, M.D. Miami Medical College, Cincinnati, 1870, died at his home in Shelbyville, Ill., March 18, from cerebral hemorrhage after an illness of two weeks.

Wylie See Athey, M.D. University of Louisville, Medical Department, 1893, died in San Francisco, December 17, and was buried in Holly Springs, Miss., December 25.

William N. Riley, M.D. Harvard University Medical School, Boston, 1901, died suddenly at his home in Malden, Mass., March 16, from heart disease, aged 26.

Marshall V. Wilson, M.D. (County license, Jackson County, Ind.), 1897, died at his home in Melora, Ind., March 18, after an illness of several weeks, aged 71.

James H. Johnson, M.D. University of Louisville, Medical Department, 1880, died at his home in Round Rock, Texas, March 15, from neurasthenia.

Francis J. Wennerberg, M.D. Harvard University Medical School, Boston, 1893, died from pneumonia, at his home in Boston, March 17, aged 37.

A. A. Chapman, M.D. Long Island College Hospital, Brooklyn, N. Y., 1872, formerly of Lawrenceville, Ga., died recently at his home in Brevard, N. C.

William Eckels, M.D. Jefferson Medical College, Philadelphia, 1837, died at his home in Mechanicsburg, Pa., March 8, from cerebral hemorrhage, aged 73.

W. H. K. King, M.D. Rush Medical College, 1878, died at his home in Carthage, Mo., March 20, from pneumonia, after an illness of one week, aged 61.

Leopold Hirschmann, M.D. Cornell University Medical College, New York City, 1899, died at his home in New York City, March 15, aged 35.

Darius Z. Bowman, M.D. College of Physicians and Surgeons of Baltimore, 1880, died at his home in Reading, Pa., March 18, from erysipelas, aged 51.

Frederick B. McKenney, M.D. University of Buffalo (N. Y.) Medical Department, 1898, died at his home in Varysburg, N. Y., March 17, aged 33.

Herbert Thomson, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1872, died recently at his home in Booneville, Cal.

Miscellany

Quack Advertisements in Great Britain.—The English periodical *Truth* has made a practice of excluding objectionable advertisements from its columns, and the *Medical Press and Circular*, in a recent issue, in referring to a particularly fraudulent case, advises the daily papers to follow the good example. The advertisement in question is that of a charlatan who advertises in the London *Daily News* that he can cure asthma, consumption, chest and stomachic complaints, and claims that he is a specialist of twenty-five years' standing in Brighton, though he offers free advice at an address in London. In commenting on this, the *Medical Press* states that the issue of so costly an advertisement indicates the large sums which are secured thereby. The insertion of such an advertisement in the columns of a daily paper, says the *Medical Press*, makes the editor of the paper *particeps criminis* in the attempt to obtain money under false pretences, and asks the editor of the paper in question what he has to say in defence of the advertisement. The *Medical Press* also suggests that editors of newspapers exclude from their advertising columns all advertisements which have been blacklisted by *Truth*.

The Journal of the Outdoor Life, which has just entered on its third year and which is the official organ of the National Association for the Study and Prevention of Tuberculosis, is an excellent advocate of fresh air and wholesome life in the prevention and treatment of tuberculosis and other diseases. It is intended for circulation among the laity, and certainly makes interesting reading and will aid greatly in the anti-tuberculosis propaganda. A distinct service which it is rendering is the pointing out of the more common errors into which the health seeker is apt to fall in the following of fads or irrational advice. It advocates competent medical supervision, fresh air, nourishing food and carefully regulated exercise. Among its contributors are the best men in the profession. We are always glad to look over this bright little periodical. It is published at the Adirondack Cottage Sanitarium, Trudeau, N. Y., at \$1 a year, and is not a money-making enterprise.

Research on Spinal Anesthesia.—P. Lazarus of Berlin contributes an article on "Lumbalanästhesie" to the *Med. Klinik* for Jan. 28, 1906. He has found spinal anesthesia a welcome relief in a number of cases of intense pain from compression of the spinal cord by a cancer or in the crises of tabes. He thinks that it may also be indicated in spastic paralysis, in tetanus, in paramyoclonia, and similar contractures. Also

it might be found useful to differentiate and treat hysterical, organic, or simulated painful contracture of the legs. A further indication is as a preliminary to mobilization of stiff joints, and for bloodless stretching of nerves. One of his patients, with severe, rebellious sciatica, was completely cured after the sciatic nerve had been stretched three times in eight days under spinal anesthesia. In another case a patient with extremely painful ankylosis of the knee after a gonorrheal affection was treated by mobilization of the joint under spinal anesthesia, the patient looking on at the manipulations without the slightest pain, three minutes after the anesthetic had been injected into the spinal cavity. Spinal anesthesia is particularly useful for this class of cases as the patient is able to make the first attempts to move the formerly painful limb, and thus learns to use it at once, instead of shrinking from using it for fear of possible pain. Neither advanced age nor cachexia contraindicate spinal anesthesia. He follows Bier's technic, described in *The Journal* for May 7, 1904, page 1260. He has been studying on 64 rabbits whether it might not be possible to induce spinal anesthesia with some substance less toxic than the standard anesthetics. He found that it was possible to arrest temporarily the sensory and motor conductivity of the spinal cord by inducing a focus of transient edematous infiltration of the spinal cord by dural infusion of saline solutions equivalent to an 8 per cent. salt solution, that is having the same osmotic tension. He found further that intradural introduction of large amounts of fluids is dangerous, and that intradural injection of air is fatal. Infusion of distilled water or of cold fluids causes great pain. Infusion of hypotonic or isotonic saline solutions or of a 25 per cent. solution of urea is indifferent. Infusion of a 10 per cent. salt solution is fatal. Infusion of an 8 per cent. solution of common salt or of magnesium sulphate has an anesthetic and paralyzing action. Spinal anesthesia with magnesium sulphate is more effectual than general anesthesia in case of strychnin tetanus, and is liable to prove a life-saving measure.

Fee Table System Injures the General Practitioner.—In former days professional fee tables were supposed to govern every member of the medical profession, but now, says Dr. D. W. Cathell in the *Medical Times*, owing to the work done by specialists and their consequent excellent reputation, as a body, the size of their fees is no longer controlled by these antiquated fee tables. Each specialist establishes for himself some more or less definite financial policy of his own, and puts his own value on his services, taking care, usually, to charge each patient enough to aid materially in giving him his and his dependents a comfortable support, with some addition for their needs when he is no longer able to work. To-day, therefore, this old fee-table method of computing fees by the visit governs only the general practitioners, and as far as the best interests of these are concerned, they govern them in the wrong direction. Dr. Cathell states that both specialists and general practitioners have cases among the worthy poor, and that they willingly give those who deserve it, "a poor man's bill," but they often get little or nothing, sometimes not even thanks, for very valuable services, occasionally for saving life itself; and that specialists and every general practitioners alike encounter transient, indefinite, chronic or minor cases in which they charge only a meagre pay-by-the-visit fee, whether by the house visit or for services at the office.

When it comes to important and well-marked cases, in which the patients are able to pay full prices, there exists a very wide and very deep chasm between the custom of the two professional bodies, for the specialist, says Dr. Cathell, then justly ignores all details and charges a bulk sum for his services, while the general practitioner, in calculating the amount of his fees for cases often equally or more important, many times involving life itself, *unjustly* limits himself to counting the number of visits made, with but little or no regard to anything else.

Dr. Cathell calls attention to the fact that the entire population is living under different financial conditions from those of the time when the fee bill was first established, and that

every practitioner should base his charges on professional ability and on the character of the demands made on it instead of on a chalk-mark account of the number of office calls or visits made. He advises every physician in America to make skill and services the basis of all his charges, taking care that the amount named shall be sufficient to cover silently all visits, detentions, distances, etc., because by so doing a physician will enhance his reputation for skill and at the same time get better returns for his work.

The Dust Menace.—For years, says Dr. H. S. Anders, in *Pennsylvania Medical Journal*, I have felt that in fighting the dust evil a most important branch of sanitary work was to be found, especially in the large cities and towns. Public adaptation in this matter is hardly more than a threshold recognition. Street dust, plush-cushion dust in trolley, regular passenger and Pullman cars, damp and dark corner and crack dust in houses, etc., is loaded with pus micrococci, and besides purulent nasopharyngeal, tonsillar, sinus, and bronchial inflammations, may be a threefold factor in pulmonary tuberculosis. First, it may act as a predisposing cause, as a direct physical irritant to the respiratory passages, thus inflaming the mucous membranes and weakening their resistance to bacillary invasion; second, it may carry infection directly by means of dried, fresh tubercular sputum that some ignorant or careless consumptive has recently expectorated; third, it may aggravate tuberculosis by converting an incipient and curable case into one of rapid and virulent destruction of lung tissue because of the addition of pus-producing germs. Pulverized poison added, a mixed infection engendered, and speedy dissolution follows. When will our municipal authorities see clearly, understand fully, and act humanely? How long must the people submit supinely to the present conditions of street dirt, insufficient sprinkling, and infantile methods of cleaning? For the fault is not entirely with rushing automobiles, grinding trolley cars, and unsophisticated Italian street sweepers. Were the dirt removed at night, and the comparatively slight remaining dust kept down during the day by sprinkling as a part of a city's duty to its citizens, these public utilities would incur less justifiable criticism.

The Cold Storage of Undrawn Poultry and Game.—Last year the New York legislature defeated a bill the substance of which was the prohibition of the cold storage of game or poultry in the undrawn state and its subsequent sale to the public. We learn that the authors of last year's defeated bill are about to introduce a similar measure again this year. The defeat of such a measure is only an instance of the strength of the so-called "beef trust." Not content with squeezing the last penny out of the public by their high charge for all the meat that is sold, they actually menace the health of communities by selling undrawn game and poultry which has been left in cold storage for an indefinite period. Undoubtedly a large percentage of the cases of toxin infection which have become so prevalent of late years are directly ascribable to cold-storage poultry.—*Medical Age*.

Source of Girault's Paper on the Bedbug.—In our editorial March 17, 1906, on the bedbug and disease possibilities, we spoke of a pamphlet by A. A. Girault as a publication of the United States Department of Agriculture. The reference we gave was wrong. The paper in question appeared in *Psyche*, Vol. XII, Nos. 3 and 4, June-August, 1905, pp. 61-74. This periodical is published by the Cambridge Entomological Club, which may be addressed in care of the Boston Society of Natural History, Boston.

Aselli.—The cluster of lymphatic glands lying in the mesentery is sometimes called the pancreas of Aselli, or lesser pancreas. These glands were described by Gaspar Aselli, an Italian anatomist, who was born in 1581 and died in 1626. His home was at Cremona. In the year 1622, while professor of anatomy at Pavia, he discovered the lacteals, and wrote a book on the subject.

Dr. Young of Glasgow.—In *THE JOURNAL*, Jan. 6, 1906, page 45, we referred editorially to the author of the article, "Gunshot Wounds of Peripheral Nerves," as Archibald Young of London. Dr. Young calls attention to the fact that his address is Glasgow, not London.

Book Notices

THE ANIMAL PARASITES OF MAN. A Handbook for Students and Medical Men. By M. Braun. Third enlarged and improved edition, with 294 illustrations. Translated from the German by P. Falck, brought up to date by L. W. Sambon, M.D., and F. V. Theobald, M.A. Cloth. Pp. 453. Price, \$5.00 net. New York: William Wood & Co.

This is the first English edition of this work, which contains 453 pages. The paper strikes one as rather inferior in quality. The book contains in convenient form an enormous amount of facts and authoritative information concerning the non-bacterial human parasites now of such growing importance not only to physicians living in warm climates, but also to those in temperate and even cold regions. Parasite carriers (mosquitoes, tsetse flies, ticks, etc.) are considered fully. The book is sure of appreciation. In the next edition the author no doubt will revise the section on trypanosoma so as to bring it in better harmony with the results of recent investigations.

PHARMACOLOGY AND THERAPEUTICS. By R. W. Wilcox, M.A., M.D., LL.D. Sixth Edition. Based on the Fifth Edition of White and Wilcox's *Materials and Therapeutics*. Cloth. Pp. 1010. Price, \$3.50. Philadelphia: P. Blakiston's Son & Co., 1906.

This is a companion book to White's *Material Medica and Therapeutics*, but it has less to commend it. On page 10 we find the following: "It is also equally true that the details of the chemical behavior of such substance can be ascertained only by performing the necessary reactions, and the point has therefore been well taken that as there is no prospect at the present time of explaining the latter from its constitution, there is still less hope that much advance will be made in the near future in formulating the laws governing the details of its pharmacological effects." To this we can not agree. Just as the chemical behavior of many substances can be stated with reasonable accuracy from a knowledge of their constitution and relationship, so much advance is being made in the study of the relation between chemical constitution and pharmacologic effect. Another criticism that may be made is that in a book intended as a text-book for use in American schools and colleges there are too many preparations of the *British Pharmacopoeia*—to say nothing of the amount of space devoted to certain proprietary remedies, of which little is known beyond the statements of the manufacturers. On page 33, in speaking of ether, the author has used the practically obsolete term "sulphuric ether." He may be severely criticised for using obsolete or unusual terms, *sal alembroth*, for example, which tend to confuse the reader. It is to be regretted that so few books designed to be used as text-books for students of medicine possess so little educational value.

SURGICAL TREATMENT OF CHRONIC SUPPURATION OF THE MIDDLE EAR AND MASTOID. By S. Oppenheimer, M.D. Illustrated by 46 half-tone plates, containing 64 figures and 27 key plates, etc. Cloth. Pp. 425. Price, \$6.00. Philadelphia: P. Blakiston's Son & Co., 1906.

This is one of the most important books that has appeared on this subject in the English language. It must, of course, be compared with McEwen's classical work and with Whiting's recent publication, but it does not suffer in the comparison, as it is more generally and practically useful than either. McEwen's book is more authoritative and learned, and in reality forms a ground work or foundation for scientific mastoid surgery, and will remain a classic to which we must always turn for counsel, but it does not touch on middle-ear surgery nor on that subject which is of enormous interest to modern otologists, the radical mastoid operation. Therefore, as a practical every-day working book Oppenheimer's production will be more frequently useful to the busy surgeon.

Whiting's artistic book on "The Mastoid Operation," while excellent as far as it goes, makes no mention of the radical operation and proved disappointing to those readers who expected a complete dissertation on the subject from one of Whiting's erudition, skill and experience. We, therefore, re-affirm that Oppenheimer's book, containing, as it does, the necessary anatomy of the temporal bone, the treatment and operative interference of the tympanum, a comprehensive chapter on "Anatomic and Surgical Landmarks," directions for the simple mastoid operations and its complications, minute instructions as to the radical mastoid operation, including most comprehensive descriptions concerning the vari-

ous plastic procedures, together with a wealth of beautiful and plain pictures that clarify the entire subject, will at once assume a position of first importance in the working library of the aural surgeon. The mechanical part of the volume is excellent, and the illustrations can not be too highly commended and they will be appreciated by those who are not well up on their anatomy. An interesting feature of the book is its plain and comprehensive chapters on suppurating middle-ear diseases and their treatment, surgical and otherwise; indeed, the only criticism that can be made on this section of the work is the feeling that the author has devoted a preponderating amount of space to these subjects; still, in these days of tendencies toward radical surgery of all kinds, it is gratifying to note the words of warning and a leaning toward conservatism. The author himself, however, is evidently "torn with conflicting emotions," for quite frequently throughout the book, while dwelling on middle-ear treatment for supuration, and going into minute details concerning ossiculectomy and curetette and emphasizing its importance at great length, he lapses into the prevailing opinion that, after all, intractable middle-ear suppurations are best treated by the radical operation. In this view he will be upheld by the best and most progressive surgeons, for, while conscientious surgeons never desire to rush unnecessarily into operative procedures, yet, considering the mortality of unchecked tympanic suppurations and the inaccessible location in the antrum and cells of most of these diseases, the radical operation is the only logical treatment in a large proportion of such cases. Nevertheless, conscientious and proper middle-ear treatment, followed perhaps by ossiculectomy, etc., should, of course, as recommended by Oppenheimer, be given a faithful and painstaking trial before so serious an operation as a radical mastoidectomy is advised. Success, however, can only be expected in those cases in which the seat of disease is limited to the tympanic cavity, and not to those instances in which necrosis, granulation, etc., have extended backward to the antrum or to the cells, and, as Oppenheimer says on page 9, it should never be forgotten "that the purulent discharge should be looked on as a symptom of the pathologic conditions present and not as the actual disease itself." The author also calls attention to the fact on page 9 that "the order of the discharge can easily be relied on as an indication of necrosed bone unless it is unusually persistent, following careful local cleansing of the tympanic cavity." It may, as he says, be due to "the presence of a retained irritating secretion or of a mass of desquamated epithelium undergoing fatty transformation." On page 185 the very interesting statement is given by Birmingham that the antrum was absent in one skull among one hundred which he examined. This observation can not fail to be of interest to all who frequently perform some form of mastoid operation, as many authors affirm positively that the antrum, though sometimes misplaced, is invariably present. Another interesting statement by Burkner is given on page 186, to the effect that he found congenital dehiscences of the tegmen antri present 167 times in 765 cases. These studies also disclosed the fact that, irrespective of age, the antrum can always be found (when present) inferior to the linea temporalis and superior and anterior to the squamo-mastoid suture.

On page 189 attention is directed to the well-known close contiguity existing between the osseous Eustachian tube and the internal carotid artery, which are separated by a thin shell of bone, which fact is instructive when the surgeon undertakes to curette the tube mouth in the radical operation with either the sharp spoon or burr, and argues in favor of pressing these instruments forward instead of backward toward the artery. On page 239 Oppenheimer states that the radical mastoid operation is not necessary in all cases of chronic purulent otorrhea, as necrotic and other changes in the antrum and cells are not always of sufficient extent to warrant this procedure. In this statement, of course, he will not be contradicted, the only problem to be solved being the existence and extent of the pathological changes of serious character within these chambers. This can easily be done in those cases accompanied by mastoid symptoms, such as pain, tenderness, swelling, temperature, etc., but what of those cases in which the mastoid is quiescent, and in which the only in-

dication is a persistent intractable discharge, which does not yield to suitable middle-ear treatment nor even to an ossiculectomy, and in which the existence of intra-mastoid disease is reasonably certain? Some light may perhaps be thrown on this perplexing question by referring to the opinions of some otologic leaders as quoted by Oppenheimer. Milligan says: "When the suppurative has persisted for twelve months, with careful local treatment for three months without avail, the mastoid should be opened." Luc advises a mastoid operation "for the cure of aural suppurative after operation by way of the meatus has failed." Schwartz operates "as a prophylactic operation to facilitate drainage in incurable fetid suppurative even with no evidence of retention." McEwan advises a radical operation to prevent the danger of future complications in cases where "pyogenic lesions exist in the middle ear or its adnexa which are either not accessible or can not be eradicated through the canal." Küster advises the radical operation in intractable otorrhea "on the general surgical principle that when a collection of pus is confined within a bony cavity the focus of infection should be freely opened in order that the morbid changes present can be seen and the pathologic tissue thoroughly eradicated." And so these opinions might be repeated and indorsed by otologic leaders throughout the world, the only question being as to when and under what circumstances an aural discharge shall be regarded as intractable, in order to announce the advent of operative mastoid advice. It is hoped that some reasonably accurate data will some day be thrown on this as yet unsettled problem, and that meanwhile the mortality reports of septic intra-cranial lesions may not be allowed to become over large.

On page 254 the rather strange advice is given to commence opening the mastoid cortex over the antrum with a gouge or drill, and then to complete the work with the chisel. On the same page the statement is made that so well-known a surgeon as Blake uses a long broad-bladed drill with which to commence the opening in the cortex. One would suppose that in this day of advanced mastoid surgery such dangerous and inadequate weapons as drills would have been relegated to the receptacle for discarded instruments. No instrument should be used for this operation whose cutting edge cannot be kept under constant observation, as in a bony shell, where the anatomic landmarks are so shifty in their location as is the case in the mastoid bone, there is no telling what the deadly and unseen end of a drill may encounter. This surgical warning is so well understood as to make it seem quite unnecessary and yet the suggestions on page 254 appear to render its utterance quite essential. Oppenheimer himself, on the same page, remarks that "the drill and the trephine are not so safe as the chisel," if this is true (and it undoubtedly is) then the reviewer would beg to inquire why should we go backward ten or fifteen years and use them? On page 257 the advice is given to use a lead-filled or compressed rawhide mallet for driving the chisels. Of course each surgeon must select his own instruments, but the reviewer would beg to suggest that a lignum vitae mallet of ample size encased in a partial overcoat of steel is superior to either a lead or a rawhide mallet. A lead mallet is too heavy if large, and too small for convenience if of the proper weight. A rawhide mallet does not strike a firm enough blow, and soon becomes soft and pulpy if boiled a few times. A large steel covered, hardwood mallet strikes a good, firm blow, and is practically indestructible.

On page 264 the author advises (in the simple mastoid operation) that the sure location of the antrum and tympanum be ascertained by passing one probe into the tympanum by way of the meatus, and another probe into the tympanum by way of the mastoid and antral cavities, and making them touch. The reviewer is of the impression that this is a questionable procedure in acute mastoid operation, as he believes it better to leave the tympanic cavity untouched in such operations for fear of injuring the ossicles, which should usually be left alone (except in the radical operation) as they are, of course, important factors in good audition, which we always expect to preserve after the simple operation.

On page 271 the author refers to the valuable qualities of the dental or electric burr in mastoid work. The reviewer believes that there can be no question of the truth of this state-

ment, the only difficulty being in securing a good, strong reliable, ever-ready machine that can be sold at a reasonable price. Jansen of Berlin uses such a machine and certainly no one can witness his operations without being impressed with their great technical beauty. As Oppenheimer says, the round bur is an extremely safe instrument in case the facial nerve, dura or sinus is encountered as its spheroidal form "pushes the tissues ahead without cutting or wounding them."

On page 273 Oppenheimer recommends the complete closure of the post-auricular wound by sutures in the acute mastoid operation, provided the operator is sure that all diseased tissue has been removed. In the first place how can one be sure that all diseased tissue has been removed, and in the second place the reviewer feels quite confident that but few experienced operators believe it wise to suture entirely an acute mastoid wound, as it is tolerably certain that such openings should be gradually healed by drainage and granulation.

Commencing on page 287 and continuing for several pages thereafter will be found a most comprehensive description of the pure mastoid operation as devised by Stacke. While this operation is now but little used, having been justly superseded by the more useful procedure called after the joint name of both Stacke and Schwartz, or usually denominated by the shorter cognomen of the "radical operation," yet a clear description of Stacke's operation as given by Oppenheimer, is not only interesting and rather unusual, but also useful, as it may, in rare cases of extreme forward displacement of the sigmoid sinus, become necessary to transpose what was intended to be a Stacke-Schwartz operation into a Stacke operation, and for this emergency the surgeon should always be prepared. The reviewer is convinced that the consensus of opinion at the present time is strongly against the performance of the pure Stacke operation, as a primary procedure for the radical cure of purulent otitis. The operation should be commenced as the well-known Stacke-Schwartz procedure and finished as such unless an extreme forward displacement of the sinus is found rendering such an operation impossible. The Stacke-Schwartz operation should then be abandoned and the antrum entered by way of the meatus and tympanum as suggested by Stacke.

On page 290 the author advises that after the posterior and superior walls of the cartilaginous meatus have been separated from their osseous attachments by a narrow periosteotomy, that the inner portion of the cartilaginous meatal tube be cut across close to the tympanum by a small knife. It has been the reviewer's experience and observation that this is never necessary as the cartilaginous meatus can be thoroughly and completely loosened by a narrow periosteotomy, and then easily released from its osseous bed by a little firm traction without the use of the knife at all.

On page 297 reference is made to a method of loosening the cartilaginous meatus, which should certainly be condemned. The author says that an incision may be made "in the upper posterior wall of the meatus, commencing at the annulus tympanicus, and from within outward; a like incision is then made along the lower part of the meatal wall, parallel and opposite to the first incision, and the flap of tissue thus included between these two incisions is separated from the osseous wall and removed with scissors, so that the posterior and superior walls of the canal are thus exposed." The author himself admits in the next line that "this method may, however, seriously interfere with any plastic operation that may be desired." This objection is certainly valid and should be a sufficient reason for not even mentioning the method as the plastic procedure following the radical operation is certainly of the utmost importance for its success, and the amputated meatal tissue thus wasted by the plan referred to by the author is the very essential tissue that will subsequently be imperatively demanded.

On page 309 will be found a timely note of warning on too great freedom in the production of unnecessary traumatism of the auricular cartilage for fear of producing perichondritis, and with it the dreadful deformity which follows. To one who has never produced this deformity this warning may seem superfluous, but to one who has met it in his own practice precautions of this character will appeal with peculiar directness.

Commencing on page 310 will be found plain and minute descriptions of the primary skin grafting methods at the time of the mastoid operation, as practiced by Dench and others; and commencing on page 333 will be found equally comprehensive directness as to the methods of the secondary grafting procedures of Ballance and others performed in from seven days to three weeks after the original operation by opening the wound, placing the grafts and reclosing the incision. As grafts applied either at the mastoid operation or later, are unquestionably necessary in some cases, these lucid descriptions of Oppenheimer are both timely and useful and should be carefully considered.

On page 330 is mentioned the method of using the Gelle saw in removing the upper, posterior wall of the osseous meatus, for the purpose of avoiding the facial nerve and horizontal semicircular canal. This fine, flexible saw is introduced by the tympanum and is drawn out through the meatus. The two ends of the saw are then held by the two hands of the surgeon, and by a to and fro movement the bridge is cut away. This method has never been witnessed by the reviewer, but it appeals to him as being a procedure that is at least worthy of a trial. The reviewer can not refrain from rather enthusiastically praising the printed descriptions and beautiful pictures of the various plastic and flap operations so well described and depicted in the latter portion of this volume. They certainly are most excellent and unusual, and should be carefully studied by all who do mastoid surgery. The same praise may be given unreservedly to the last chapter of the book on the "After Treatment of Mastoid Operations," which is a most important subject and one which is frequently neglected by authors, and yet one that is absolutely essential to the surgeon who is looking for the best ultimate results.

On page 394 will be found some very interesting and encouraging statistical figures on the result of the radical operation on hearing, about which much uncertainty prevails in the minds not only of general practitioners but of aural surgeons as well. It seems that Grossman has compiled the records of the after history of 216 cases of radical mastoid operations, and has found that with an intact labyrinth about 48 per cent. of the patients showed an improvement of hearing, in about 20 per cent, there was no change, and in about 31 per cent the hearing power was diminished. This shows, therefore, that in about 68 per cent. of the cases the function of audition is either improved or unimpaired. This is certainly most encouraging to the operator and to the patient, especially when it is considered that the operation is indicated in cases of intractable aural suppuration in order to eliminate a vital menace and that the hearing power must take second rank as a prognosticating consideration.

The reviewer again begs heartily to indorse Dr. Oppenheimer's timely and excellent work and to recommend it not only to all otologic surgeons but to general practitioners as well, believing that the book can be advantageously and profitably read and studied by both.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

ATTENDING CHILDRENT AFTER ATTENDING ERYSIPELAS.
ORLANDO, OKLA., March 17, 1906.

To the Editor:—Is it safe to go at once into a case of labor, after discharging a case of erysipelas, provided the accoucheur thoroughly sterilizes himself and his clothing, or should one wait a few days? I practice in the country, and have just been in two cases of erysipelas for the past two weeks, discharging the last one today. I am expecting several confinements that may come off any time after this writing, and I wish to know if I take a bicloride bath, including my hair, and change my underclothing and expose my outer clothing to sulphur fumes for six or eight hours in a closed room will I be safe in going into these labor cases immediately thereafter, or should I wait a few days, and if so, how long?

Wm. H. WALKER, M.D.

ANSWER:—When a physician has charge of a case of erysipelas, superficial fever, pyemic abscess or other infection the degree of contamination of his body and clothes depends much on his method of

handling the case of infection. He may contaminate his clothing by bringing it in direct contact with the diseased body or its secretions or indirectly by contaminating his hands and then handling his clothes. If he carefully avoids contaminating his clothes by protecting them with a large apron and by disinfecting his hands immediately after contamination before touching any part of his clothing he will avoid a good share of the danger from infectious cases. Likewise the contamination of the body of the physician may be avoided to a considerable extent. He should not remain in close proximity to the patient longer than is necessary. He should especially avoid getting his hair or beard contaminated. He should protect his hands while dressing abscesses, etc., with rubber gloves. In case he does contaminate his hands he should disinfect them at once, and not leave the contamination material long in contact with the skin. If these precautions have not been taken he may assume a thorough contamination of himself and his clothes. Will such a thorough cleaning as our correspondent specifies be sufficient to remove all pathologic germs? There is no question that the clothes can be rendered safe. The great danger is in the hands, which have been especially contaminated. Probably no combination of mechanical and chemical disinfection can be devised that in the course of 10 to 20 minutes can certainly effectually sterilize the badly contaminated fingers. Here three or more efforts at disinfection separated by an interval of several hours is desirable just as "fractional sterilization" in the laboratory is necessary. In cases of great emergency a thorough change of clothes and a hot bath, including a head bath and the most careful possible cleaning of the hands, with the use of rubber gloves, are justifiable. The danger occurs in the failure to carry out these rules with an "aseptic conscience."

FORMULA FOR NOBLE'S ENEMA.

S. C. asks for "Noble's formula for enema." This was published by Dr. C. P. Noble of Philadelphia, several years ago, and was called a purgative enema. Originally, it consisted of magnesium sulphate, 2 ounces, glycerin 2 ounces, turpentine $\frac{1}{2}$ ounce, and water enough to make 4 ounces. This enema was recommended for use when there was difficulty in securing a movement of the bowels after abdominal sections. Now, as a rule, more water is used; at present, enough to make half a pint, or even a pint, and it is given through a high rectal tube. Dr. Noble states that this formula and enemas of a solution of alum are the two which have given him the most positive results in cases of paralytic bowel.

THE DOCTOR'S THREE FACES.

NORTH YAKIMA, Wash., March 17, 1906.

To the Editor:—Please send me the Latin verse referring to the doctor as a god, an angel and a devil; also the translation. I think that this appeared in THE JOURNAL about two years ago, but I have no copy of THE JOURNAL of that time.

CHARLES E. KEELER, M.D.

ANSWER.—Our correspondent evidently refers to an answer to a similar query published in this department, April 16, 1904, p. 1023. The epigram in question is credited to Enrius Cordus, a physician of the early part of the sixteenth century. It is as follows.

Tres medicus facies habet; nam quando rogatur
Angelum mos est, cum juvet, ipse Deus.
Post ubi curato, poscit sua premia, morbo
Horridus apparet; ferribisque Satan.

This may be very freely translated to read:

Three faces has the doctor; when first sought
An angel's—and a God's, the cure half wrought;
But when the cure complete he seeks his fee
The devil looks less terrible than he.

QUININ AS A SPECIFIC IN PNEUMONIA.

ORANGE, N. J., March 18, 1906.

To the Editor:—I was interested in reading your editorial in THE JOURNAL, March 17, concerning quinin as a specific in pneumonia. I wonder if it is generally known among American physicians that in the last few years digitalis has been largely used in Europe for the same purpose. Traube and Rehn studied the power of this drug to render the lung tissue anemic, when given in large doses, but a practical application was lacking till Petresco and Maragliano in Italy began to use digitalis on an extensive scale with excellent results. Experiments showed a decidedly deleterious effect on pneumonia toxins; and in cultures *in vitro* the development of Fréinkel's diplococcus was totally prevented. The average dose of digitalis is from 8 to 12 grams in three or four days, the treatment being then suspended owing to the cumulative properties of the drug. An improvement in the patient's condition generally begins on the second day, the pulse becoming less rapid. In rare cases, intolerance is manifested by irregularities of the pulse, nausea, vomiting and persistent diarrhea. Prescriptions generally include infusion of digitalis, aromatics, and a syrup. I should be very glad to hear whether or not any of your readers have had any experience in this line. C. D. MARTINETTI, M.D.

ANSWER.—In the editorial referred to, we made specific mention of Petresco and his use of digitalis. Numerous articles on the treatment of pneumonia with digitalis can be found if one takes the trouble to go back over the literature of the last fifteen years.

for Petresco wrote as far back as 1891 (*Therapeutische Monatshefte*, February, 1891). The treatment has been tried by many clinicians in many lands, and the results have not proved Petresco's claim for large doses of digitalis as a routine and nearly specific plan of medication in pneumonia. By consulting the *Index Medicus* or our own Index of Current Medical Literature one may learn that the digitalis treatment is old and that the remarkable claims made for it can not be substantiated.

OBJECTION TO THE SECURING OF PURE FOOD LAWS.

CAVE-IN-ROCK, ILL., March 23, 1906.

To the Editor:—I hand you herewith a lost sheep which has wandered back close to home and jumped into my premises this morning. As you will see by the envelope, it traveled incognito, and it makes no difference where it goes just so it goes somewhere, so I refer it to you for identification. I call it a "What Is It."

ANSWER.—The "What Is It?" enclosed by Dr. W. J. J. Paris is a reprint of an article entitled "The Wholesale Poisoning Scare," by R. G. Eccles, M.D., of New York City. It is a reply to an excellent paper which appeared in the *Medical Fortnightly* last October, written by Dr. C. F. Wahner, Ft. Madison, Iowa. Evidently, something has broken loose in regard to this and several other matters that relate to preservatives, etc., for Eccles' paper appeared last November and is now reprinted and is evidently very widely circulated, for we are receiving copies of it from all parts of the country. The question arises: "Who pays the freight?"

State Boards of Registration

COMING EXAMINATIONS.

- UTAH State Board of Medical Examiners, Salt Lake City, April 2. Secretary, R. W. Fisher, Salt Lake City.
- ARIZONA Board of Medical Examiners, Phoenix, April 2-3. Secretary, Ancel Martin, Phoenix.
- CALIFORNIA Board of Medical Examiners, San Francisco, April 2-3. Secretary, Charles L. Tisdale, San Francisco.
- ILLINOIS State Board of Medical Examiners, Peotelleo, April 3. Secretary, J. D. Conant, Jr., Geneseo.
- MISSOURI State Board of Medical Examiners, Senate Chamber, the Capitol, Helena, April 3. Secretary, William C. Kiddell, Helena.
- NORTH DAKOTA State Medical Examining Board, Grand Forks, April 3. Secretary, H. M. Wheeler, Grand Forks.
- OHIO Board of Registration and Examination, State House, Columbus, April 3. Secretary, D. N. Kinsman, Columbus.
- MINNESOTA State Board of Medical Examiners, State Capitol Building, St. Paul, April 3-5. Secretary, O. E. Linjer, Minneapolis.
- RHODE ISLAND State Board of Health, State House, Providence, April 5. Secretary, Gardner T. Swarts, Providence.
- GEORGIA Medical Examining Board (Regular), the Capitol, Atlanta, first week in April. Secretary, E. R. Anthony, Griffin.
- ARKANSAS State Board Medical Society, Little Rock, April 10. Secretary, J. P. Runyan, Little Rock.
- MISSOURI State Board of Health, Barnes Medical College, St. Louis, April 10-12. Secretary, J. A. B. Adcock, Warrensburg.
- WEST VIRGINIA State Board of Health, Parkersburg, April 10-12. Secretary, H. A. Barbee, Point Pleasant.
- DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, D. C. April 12. Secretary, William C. Woodward, Washington, D. C.
- MISSOURI State Board of Health, University Medical College, Kansas City, April 16-18. Secretary, J. A. B. Adcock, Warrensburg.
- ILLINOIS STATE BOARD OF HEALTH, Northwestern University Building, Chicago, April 18-20. Secretary, J. A. Egan, Springfield.

Oklahoma December Report.—Dr. J. W. Baker, secretary of the Territorial Board of Medical Examiners, reports the written examinations held at Guthrie, Dec. 27, 1905. The number of subjects examined in was 10; total number of questions asked, 90; percentage required to pass, 66.6 in each branch. The total number of candidates examined was 17, of whom 8 passed and 9 failed. The following colleges were represented:

	PASSED.	Year Grad.	Per Cent.
College.			
Electric Med. Univ., Kansas City.....	(1905)		68
University of Missouri.....	(1905)		76
Rush Med. Coll.....	(1904)		76.5
University of Iowa.....	(1903)		72.6
Dewey & Gross Coll. of Med.....	(1903)		74.8
University of Nashville.....	(1896)		78.8
Medical-Chirurgical Coll., Kansas City.....	(1903)		74.3
Columbian University.....	(1902)		92.7
	FAILED.		
Kookuk Coll. of P. & S.....	(1904)		60.8
Rush Med. Coll.....	(1889)		70.1
Vanderbilt University.....	(1905)		67.6
Kookuk Med. Coll.*.....	(1898)		
College of P. & S., St. Joseph, Mo.....	(1894)		59.8
Physio-Med. Coll., Illinois.....	(1897)		50
College of P. & S., St. Joseph.....	(1882)		65
University Med. Coll., Kansas City.....	(1905)		64
University of Iowa.....	(1881)		70

* Dropped out before finishing last two subjects.

Rhode Island January Report.—In the report of the examination held at Providence in January, 1906, published in THE JOURNAL, Feb. 10, 1906, page 453, among the failures was one candidate stated to be a graduate of the Medico-Chirurgical College, Pennsylvania. Later reports show that this man was an undergraduate.

Washington January Report.—Dr. C. W. Sharples, secretary of the State Medical Examining Board of Washington, reports the examination held at Spokane, Jan. 2-4, 1906. The number of subjects examined in was 15; total number of questions asked, 100; percentage required to pass, 75; graduates over 10 years, 70. The total number of candidates examined was 73, of whom 53 passed and 20 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University Coll. of Med., Virginia.....	(1905)		84
Alexander University, Helsinki, Finland.....	(1907)		82

*Part of examination papers lost and exact grade not assignable.

†Second failure.

‡Third failure.

§Fourth failure.

¶Fifth failure.

The following questions were asked:

MEDICAL JURISPRUDENCE AND PREVENTIVE MEDICINE.

1. Name one or more conditions in which a doctor could be held liable on account of errors in (a) diagnosis, (b) surgery, (c) obstetrics. 2. Give the signs of corrosive poisons before and after death. 3. In case of poisoning, what evidence can be obtained from blood? 4. Give the method of examination and findings. 4. Suppose a new-born baby were found dead and infantile death had not been murdered? 5. What is understood by the law by the term "infantile death"? 6. What means should be used to prevent poisoning among workers in lead? 7. Name the manner of dissemination and means of prevention of tuberculosis. 8. Name the manner and means of dissemination of Asiatic cholera and method of prevention, specifying two chemical and two physical means. 10. What means should be taken to secure a pure milk supply? Name the amount of solid material and the percentage of bacteria per cent that indicates danger and impurities. Name the dangers of an impure supply.

GYNECOLOGY AND OBSTETRICS.

1. Give the sequelae of gonorrhea in the female. 2. Give in a concise statement your method of examining the female pelvic organs. 3. Enumerate the different uterine displacements. Give the cause of each and a method of correcting the same. 4. Define ectopic pregnancy. What is it indicated and give method of performing same. 5. What is atresia vagina? Give causes and treatment.

6. Draw a diagram of the female pelvis at the superior straight, showing the diameters and giving the measurements. 7. Give your method of applying forceps. State when indicated. 8. How do you treat a retained placenta? Give the dangers arising from the same. 9. What changes in the symptoms of pregnancy occur on the death of the fetus? 10. Describe the influence of pregnancy on cardiac lesions.

ANATOMY AND PHYSIOLOGY.

1. Name the muscles which move the shoulder joint, giving their origin, insertion and nerve supply. 2. Describe the peritoneum and its relation to the abdominal organs. 3. What vessels unite to form the portal vein? Into what does it divide? How does blood from the portal vein reach the heart? 4. Give the origin, distribution and function of the fascia lata. 5. Give the origin, distribution and function of the pulmonary artery. 6. Give the origin, course and distribution of the sciatic nerve. How does the external branch reach the foot of the leg? 7. Name the bones of the arm and give their articulations. 8. Describe the elimination of urine. 10. Give the physiology of the perception of light. 11. Describe in detail the difference between inspired and expired air. 12. Describe in detail the condition of the blood before expiration. 13. Give the physiology of reflex action. 14. Describe the digestion of fat. 15. Describe the development of a red blood-cell.

CHEMISTRY AND TOXICOLOGY.

1. Define acids, bases, salts and metals. 2. State the composition of atmospheric air. What do you understand by humidity and porosity? 3. Compare common (b) oxygen as to occurrence and properties. 4. What is marsh gas? Where is it found in nature? Give its chemical formula. 5. Give the chemical formula for (a) blue vitriol, (b) copperas, (c) Epsom salts, (d) Glauber's salts. 7. Give of Paris. 6. What are symptoms of (a) chlorhydrate poisoning, 8. What is one physiological action for poisoning by methyl alcohol? 9. Give treatment for morphia poisoning. 10. Give symptoms of and treatment of cocaine poisoning.

HISTOLOGY, PATHOLOGY AND BACTERIOLOGY.

1. (a) What are the four cardinal indications of inflammation? (b) Give process of and termination of simple inflammation. 2. Describe through its various stages the structural changes of the spinal cord in typhoid fever. 3. Differentiate: Fatty infiltration and fatty degeneration. 5. Name and describe two varieties of glands found in the stomach. 6. Give the microscopic structure of the parotid gland. 7. Define a Malpighian corpuscle. Give a description of the same. Name and briefly describe as to growth and function of the same. Give a satisfactory method of which each kind genic to man, and name disease or diseases with which each kind is associated. 9. Describe step by step a satisfactory method of staining suspected bacilli for tubercle bacilli. 10. What is Widal reaction? Give the method of applying and its diagnostic import.

PRACTICE OF MEDICINE AND DISEASES OF CHILDREN.

1. Give symptoms, diagnosis and prognosis of bubonic plague. 2. Give etiology, pathology, symptoms, diagnosis and treatment of common cold, acute coryza. 3. Give diagnosis of pneumonia, hydropneumothorax and pyopneumothorax. 4. Give etiology, symptoms and acute cholangitis (non-surgical). 5. Give etiology, symptoms and treatment of exophthalmic goiter. 6. Give etiology, symptoms and treatment of acute tonsillitis. 8. Give symptoms, diagnosis and treatment of pernicious anemia. 9. Give diagnosis and treatment of syphilis. 10. Give capacity (amount of food) of a child's stomach at birth, two, three, six months, six months and eighteen months. 11. Give etiology, symptoms, diagnosis, prognosis and treatment of ascites in infants. 12. Give symptoms and treatment of acute inflammation of the ear. 13. Give etiology, symptoms and treatment of acute eczema of face in infants. 14. Give diagnosis and treatment of acute vulvitis in children. 15. Give etiology and treatment of acute conjunctivitis in children.

MATERIA MEDICA AND THERAPEUTICS.

1. How do straphanthus and digitalis differ in physiologic action? Name the dose of the tincture of each. 2. What are the physiologic actions of (a) straphanthus? Name its incompatibles and its antidote. 3. Give the official preparations of rhubarb and their doses. 4. What is the active principle of scammony. 4. (a) What are the preparations of ipecac and the doses? (b) Of what is nuxvomica composed of ipecac and the doses? 5. Contrast the action of ergot and digitalis. 6. What is the action of belladonna, and what are its preparations? 7. Explain the action of opium. 8. What is the action of (a) Dover's powders, of opium. 9. What are counter-irritants? Explain (b) Fowler's solution and the rationale of their use in disease. Enumerate four in the order of efficiency. 10. Give the method of elimination and end product of (a) ether, (b) salol, (c) iodid of potash, (d) methylene blue, (e) cella.

NERVOUS DISEASES AND DISEASES OF THE EYE AND EAR.

1. Name two organic diseases of which Acryll-Robertson pupil is a frequent and important diagnostic symptom. 2. Name three forms of strabismus. 3. Give the conditions of the lower extremities, right and left, and describe the condition of the lower extremities. 3. If a patient complains of a pain in his head, dizziness and vomiting, all of which symptoms had existed for two or three months, what condition would you suspect? 4. In right-sided hemiplegia, what condition would you suspect? 5. In right-sided hemiplegia, why. 5. Give the prognosis of (a) brain tumor, (b) facial palsy, (c) acute chorea, (d) acute anterior poliomyelitis, (e) cerebral palsy of (f) acute meningitis, (g) acute encephalitis, (h) acute encephalitis. 6. By what lesion of the eye can a diagnosis of chronic neuritis be made? 7. Give the etiology, symptomatology and diagnosis of trachoma, and give the method of treatment. 8. (a) What is chalazion and its treatment? 9. Name three diseases of the eye and auditory canal and their respective treatment. 10. Enumerate the instruments that the general practitioner should have for examining the ear, and describe the best method of examination and the appearance of the parts in health.

SURGERY.

1. What method would you employ in the treatment of talipes in an infant? At what age would you begin? 2. Give symptoms and diagnosis of an impacted fracture of the neck of the femur, including in detail all the landmarks employed in the differential diagnosis. 3. Give etiology and treatment of an ununited fracture of a long bone. 4. Name types of fistula in ano, and describe the methods of treating the same. 5. Give symptoms, diagnosis, prognosis and treatment of fracture of the base of the skull. 6. What are the more common accidents of anesthesia, and how would you combat them? 7. Name three types of sarcoma. Give the more common location of each and the general characteristics of one only. 8. Give in detail the treatment of strangulated hernia. 9. Give the etiology, pathology and treatment of varicose ulcers. 10. (a) Give the differential diagnosis between chancre, chancroid and herpes preputialis. (b) Give in detail the proper treatment of syphilis.

HOMOEOPATHIC MATERIA MEDICA.

1. Define polychrest, potency, dilution, trituration. 2. Differentiate between phytolacca and kalmi bali, in angina faucium. 3. Select three remedies useful in cholera infantum. Give symptoms calling for each. 4. Give prominent symptoms of baptisia, rhus, Bryonia, and gelsemium in typhoid fever. 5. Differentiate the heart symptoms of digitalis, cactus grandis, spigella, and kalmia lat. 6. Differentiate the gastric symptoms of ipecac, antimonium tart., and arsenicum. 7. Give mental symptoms of each of the following remedies: Stramonium, hyoscyamus, ignatia, aurum, calcarea carb. 8. Select three remedies useful in dysmenorrhoea. Give symptoms calling for each remedy. 9. Differentiate the rheumatic symptoms of rhus, bryonia, colchicum. 10. Differentiate the skin symptoms of apis, rhus and silicea.

ECLECTIC MATERIA MEDICA AND THERAPEUTICS.

1. Classify the agents acting on the respiratory tract, and name three of each class. 2. Name five agents to act on the stomach, and give the properties of each agent named and the indication for its use. 3. Name three agents to act on the pancreas, liver and intestines, specifying a stimulant and a relaxant for each. 4. What agents influence the character of the blood? Name at least six. 5. What remedies would you use in treating a case of spermatorrhea and nocturnal emission? Which remedies would you use in chlorosis? 6. Name the agents you would use in expelling oxyuris vermicularis to obtain their ultimate extinction. 7. Give the treatment for an aggravated case of bronchitis with profuse expectoration, and also for one in which there is a dry and irritable cough. 8. Give in detail the treatment of cerebrospinal meningitis. 9. What means and agents would you employ in treating a case of chronic articular rheumatism? What results would you expect? 10. Give a brief synopsis of treatment of lobar pneumonia, naming all the agents you would use.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending March 24, 1906:

Hall, John D., asst.-surgeon, retired from active service, March 17, 1906.

Chamberlain, W. P., asst.-surgeon, having reported arrival at San Francisco, Cal., will proceed to and take station at Jackson Barracks, Ark., for duty.

Little, Wm. L., asst.-surg., relieved from duty at Jackson Barracks, La., and ordered to Fort Sam Houston, Texas, for duty.

Carswell, R. L., asst.-surgeon, having reported his arrival at San Francisco, Cal., will proceed to and take station at Depot of Recruits and Casuals, Fort McDowell, Angel Island, Cal. Gape, Nelson, asst.-surgeon, relieved from duty at Depot of Recruits and Casuals, Angel Island, Cal., and ordered to Columbus Barracks, Ohio, for duty.

Carswell, R. L., asst.-surgeon, granted 30 days' leave of absence. Carroll, James, asst.-surgeon, detailed to represent the Medical Department of the Army at the annual meeting of the Louisiana State Medical Society, New Orleans, La., from May 8 to 16, 1906.

Randy, Charles M., surgeon, relieved from duty at Fort Wayne, Mich., and ordered to West Point, N. Y., for duty, to relieve Lieut.-Colonel H. O. Perley, deputy surgeon general.

Perley, H. O., deputy surgeon-general, relieved from duty at U. S. Military Academy, West Point, N. Y., and ordered to the Philippine Islands, where, on arrival, he will report to commanding general, Philippines Division, for assignment to duty.

Hammond, William G., dental surgeon, relieved from duty in the Philippines Division and ordered to the United States on the first transport after July 1, 1906.

Long, Stephen M., contract surgeon, left San Francisco, Cal., on leave of absence for one month.

McNulty, Wm. W., contract surgeon, ordered from Fort Trumbull, Conn., to Fort Terry, N. Y., for temporary duty.

Sugers, Frank, contract surgeon, granted leave of absence for two months.

Tuker, William H., contract surgeon, granted an extension of seven days to his leave of absence.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending March 24, 1906:

Zalesky, W. J., asst.-surgeon, detached from the *Yankee* and ordered to the *New York*.

Campbell, P. E., asst.-surgeon, detached from the *Newport*, and ordered home to wait orders.

Proyer, E. M., P. A. surgeon, orders of March 5 revoked; detached from the Naval Medical School, Washington, D. C., and ordered home to wait orders.

Greive, C. C., asst.-surgeon, detached from the *Frolic* and ordered to the *Wilmington*.

Flint, J. C., asst.-surgeon, ordered to the *Franklin*.

Cohn, I. F., asst.-surgeon, ordered to the Naval Hospital, Norfolk, Va.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending March 21, 1906.

Austin, H. W., surgeon, granted four months' leave of absence, from March 28, 1906, with permission to go beyond sea.

Young, G. H., P. A. surgeon, directed to report to Asst.-Surgeon General W. J. Pettus, chairman of board of examiners, April 2, 1906, at Washington, D. C., to determine his fitness for promotion to grade of surgeon.

Wickers, H. W., P. A. surgeon, leave of absence granted for two days from March 16, 1906, revoked.

Lavender, C. H., P. A. surgeon, relieved from duty at Stapleton, N. Y., and directed to proceed to Detroit, Mich., and assume temporary command of service during the absence of Surgeon H. W. Austin.

Boggers, J. S., asst.-surgeon, relieved from duty at Cape Charles Quarantine Station and directed to proceed to Stapleton, N. Y., reporting to the medical officer in command for duty and assignment to quarters.

Collins, Geo. L., asst.-surgeon, relieved from duty at Reedy Island Quarantine Station and directed to proceed to Cape Charles Quarantine Station and assume command of the service.

Long, H. P., asst.-surgeon, granted leave of absence for seven days from March 10, 1906, under paragraph 191 of the regulations.

Valin, Hugh, asst.-surgeon, relieved from duty at Baltimore, Md., and directed to proceed to Reedy Island Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

Primrose, R. S., acting asst.-surgeon, granted leave of absence for 30 days, from March 18, 1906.

McKay, Malcolm, pharmacist, granted one day's leave of absence.

BOARD CONVENE.

A board of medical officers was convened to meet in Baltimore, Md., March 21, 1906, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon L. L. Williams, chairman; Asst.-Surgeon W. H. Frost, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon-general, Public Health and Marine-Hospital Service, during the week ended March 23, 1906:

SMALLPOX—UNITED STATES.

California: San Francisco, March 3-10, 7 cases.
Delaware: Wilmington, March 10-17, 3 cases.
Florida: Jacksonville, March 10-17, 3 cases.
Georgia: Augusta, March 12-19, 2 cases.
Indiana: Indianapolis, March 11-18, 1 case.
Louisiana: New Orleans, March 10-17, 12 cases; Shreveport, 1 case.

Maine: Biddeford, March 10-17, 6 cases.
Maryland: Baltimore, March 10-17, 5 cases.
Missouri: St. Louis, March 10-17, 3 cases, 1 death.
Montana: Broadwater County, Feb. 1-28, 2 cases; Lewis and Clark County, 1 case; Missoula County, 2 cases; Silver Bow County, 1 case.

New York: Buffalo, 1 case.
North Carolina: Nineteen counties, Dec. 1-31, 374; 23 counties, Jan. 1-31, 438 cases.

Ohio: Cincinnati, March 9-16, 3 cases; Hamilton, Feb. 10-17, 1 case.
Tennessee: Knoxville, March 10-17, 1 case; Memphis, March 3-17, 5 cases.

West Virginia: Wheeling, March 10-17, 6 cases.
Wisconsin: Appleton, March 10-17, 2 cases; Beloit, March 3-10, 1 case; Milwaukee, March 3-17, 3 cases.

SMALLPOX—FOREIGN.

Africa: Capetown, Jan. 27-Feb. 10, 7 cases.
Brazil: Rio de Janeiro, Feb. 11-18, 3 cases.

Canada: Grand Falls, N. B., March 15, 18 cases; Winnipeg, March 3-10, 1 case.

Germany: Bremen, Feb. 24-March 3, 1 case.
Gibraltar: Feb. 25-March 4, 9 cases, 1 death.

Great Britain: Leeds, March 3-10, 1 case; London, Feb. 17-March 4, 4 cases.

Greece: Athens, Feb. 6-20, 5 deaths.
India: Calcutta, Feb. 3-10, 141 deaths; Karachi, Feb. 11-18, 23 cases, 8 deaths; Madras, Feb. 10-16, 36 deaths; Rangoon, Feb. 3-10, 50 deaths.

Malta: Feb. 18-24, 1 case.
Mexico: Tuxpan, Feb. 27-March 6, 5 deaths.

The Netherlands: Rotterdam, Feb. 25-March 3, 1 case, 1 death.
Russia: Moscow, Feb. 10-24, 22 cases, 5 deaths; Odessa, Feb. 17-March 3, 25 cases, 3 deaths; St. Petersburg, Feb. 17-24, 4 cases, 3 deaths.

Spain: Barcelona, Feb. 19-March 1, 6 deaths; Tarragona, Feb. 25-March 3, 1 death.

Turkey: Alexandria, Feb. 17-24, 15 cases; Constantinople, Feb. 18-25, 2 deaths; Izmir, February 17-March 1, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 1-18, 9 cases, 3 deaths.
Mexico: Merida, Feb. 24-March 5, 2 cases.

CHOLERA—INSULAR.

Philippine Islands: Manila, Jan. 20-27, 3 cases, 2 deaths; Provincias, 348 cases, 247 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Feb. 3-10, 83 deaths; Rangoon, 3 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Feb. 11-18, 5 cases, 1 death.
India: General, Jan. 27-Feb. 10, 19,232 cases, 10,932 deaths; Calcutta, Feb. 3-10, 50 deaths; Karachi, Feb. 11-18, 6 cases, 8 deaths; Madras, Feb. 10-16, 9 deaths; Rangoon, Feb. 3-10, 20 deaths.

Medical Organization

Connecticut.

BRISTOL MEDICAL ASSOCIATION.—This association effected permanent organization February 13, adopted constitution and by-laws, and elected Dr. William W. Horton, president; Dr. George S. Hull, vice-president; Dr. Arthur S. Brackett, secretary and treasurer, and Drs. Herbert D. Brennan, Fred W. Deichman and William M. Curtiss, censors.

COLLINGSVILLE MEDICAL SOCIETY.—This society was organized February 14, with the following officers: President, Dr. George F. Lewis, and secretary, Dr. E. A. Hotchkiss.

NORTH HARTFORD COUNTY MEDICAL SOCIETY.—Physicians of the northern part of Hartford County met at Thompsonville, February 16, in response to an invitation from Dr. Edward F. Parsons. Temporary officers were elected as follows: President, Dr. Edward F. Parsons, Thompsonville; secretary, Dr. Myron P. Robinson, Windsor Locks, and treasurer, Dr. John L. Bridge.

Georgia.

DECATUR COUNTY MEDICAL SOCIETY.—This society was recently organized at Bainbridge, on the standard plan. Dr. Vega Berry was elected president; Dr. Gordon Clason, vice-president, and Dr. Henry H. Cheatham, secretary and treasurer, all of Bainbridge.

HANCOCK COUNTY MEDICAL SOCIETY.—The physicians of Hancock County met February 27 with Dr. W. W. Pilcher, Warrenton, councillor for the tenth district, at Sparta, and organized this society on the standard plan. The following officers were elected: President, Dr. R. C. Wiley, Sparta; vice-president, Dr. R. G. Stone, Linton; secretary and treasurer, Dr. James G. Harrison, Sparta; censors, Dr. R. G. Pattillo, Culverton; Horace R. Darden, Sparta, and R. L. Ray, and delegate to the state association, Dr. Alexander F. Durham, Sparta.

Indiana.

TWELFTH DISTRICT MEDICAL SOCIETY.—The first annual meeting of this society was held in Fort Wayne, March 13, on call of Dr. A. E. Bulson, Jr., Fort Wayne, councillor for the twelfth district. The following officers were elected: President, Dr. William H. Myers, Fort Wayne; vice-presidents, Drs. Luzerne H. Cook, Bluffton, and Frank Broughton, Waterloo; secretary, Dr. Kent K. Wheelock, Fort Wayne, and treasurer, Dr. Walter F. Carver, Albion. The society adopted the following resolutions regarding the concentration of the medical colleges of the state into one large college at Indianapolis, to be operated under state auspices through Purdue University:

Resolved, That in view of the fact that the Indiana Medical college buildings and equipments have been donated to the state of Indiana through Purdue University, conditioned only on the maintenance of a complete medical school in Indianapolis under state control, we believe it the duty of the state to make its title to this property good by the remaining legal step, namely, legislative approval of a gift especially fitted for medical college purposes and worth over \$100,000.

Resolved, That this society will use its influence in every possible way to further the interest of this school and will view with disfavor any attempt to antagonize the action taken, and that we are unable to see any good reason for opposition of the accomplishment of this long-desired purpose, and can only recognize opposition as being the expression of disappointed individual ambition or a jealous rivalry founded on a false idea as to the effect on the interests of other institutions.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5 S.

Medical Association of the District of Columbia, Washington, April 3.

Tennessee State Medical Association, Memphis, April 10.

Medical Association of the State of Alabama, Birmingham, April 17.

Medical Society of the State of California, San Francisco, April 17-19.

Florida Medical Association, Gainesville, April 18.

Medical Association of Georgia, Augusta, April 18.

Mississippi State Medical Association, Jackson, April 18.

South Carolina Medical Association, Columbia, April 18.

State Medical Association of Texas, Fort Worth, April 21-26.

Arizona Medical Association, Phoenix, April 21-25.

Medical and Chirurgical Faculty of Maryland, Baltimore, April 1-26.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Sixteenth Annual Meeting, held at Pittsburg, March 19, 1906.

The President, Dr. S. C. JAMES, in the Chair.

Officers Elected.

The following officers were elected to serve for the ensuing year: President, Dr. George M. Kober, Washington, D. C.; vice-presidents, Drs. F. C. Waite, Cleveland, and H. W. Loeb, St. Louis; secretary-treasurer (re-elected), Dr. Fred C. Zapffe, 1764 Lexington Street, Chicago; judicial council, Drs. W. J. Means (chairman), 715 North High Street, Columbus, Ohio; R. Winslow, Baltimore; T. H. Hawkins, Denver; H. B. Ward, Lincoln, Neb.; Eli H. Long, Buffalo; B. D. Myers, Bloomington, Ind.; J. M. Flint, San Francisco.

In his address as president, Dr. James urged the establishment of uniform requirements and curricula by all medical colleges, thus furthering the work now being done by state boards having in view interstate reciprocity.

Credit for Baccalaureate Degrees.

DR. CHARLES MCINTIRE, Easton, Pa., favored giving credit in the medical course for work done in the literary college.

DR. FREDERICK S. LEE, Columbia University, is convinced that it is hardly possible for medical subjects to be taught efficiently in the literary school. The object of the training given by the college is fundamentally different from that given by the medical school, and this difference connotes a difference in method. The college gives the general development that is helpful in obtaining the special equipment and making proper use of it. That the ends of the medical training may be secured, it is above all things essential that the knowledge acquired by the student in the school of medicine be exact, specific, abundant, and always at the service of the individual. In these respects the training of the college is markedly inferior. The so-called medical subjects are taught in the literary college as pure sciences, while in the medical college they are taught as applied sciences. Many of the subjects contained in the medical curriculum are taught excellently in the literary college, but they can not serve a greater purpose than that of being introductory to the work taught in the medical school. Therefore, Dr. Lee believes that no credit shall be allowed by the medical schools for work done in strictly medical subjects in literary colleges, except in occasional specific instances and for unusually cogent reasons. If the literary colleges are able to give substantially the same courses as those given by the medical schools, there can be no objection to the substitution but, humanly speaking, that is an impossibility. Further more, it would be a mistake for the literary colleges to attempt to compete with the medical schools in the field of the latter. They are not equipped properly and from the nature of the case they can not be equipped properly with spirit, instructors or method for professional training and the latter, if under taken by them, can only be unsatisfactory and inadequate. The medical school is the proper place for medical instruction.

DR. F. C. WAITE, Western Reserve University, is of the opinion that some of the courses given in the medical school can be taught fully as well, and in some instances better, by the literary college than by the medical college. He mentions particularly osteology, elementary physiology, inorganic chemistry, bacteriologic technic and the bacteriology of non-pathogenic bacteria, and the principles of embryology, or about 700 hours of the first year of the medical course.

PROF. C. JUDSON HERRICK, Denison College, stated that few colleges are prepared to do any work in this direction, nor is there any evidence of an intention on their part to attempt to do this work until the medical colleges state specifically what they will accept as the equivalent of the work done by them.

Examining Boards and Medical Colleges.

DR. B. D. HARRISON, Detroit; DR. B. F. BAILEY, Lincoln, Neb., and PROF. C. F. WHEELLOCK, Albany, discussed how medical colleges can be of service to registration and examining boards. As the result of this discussion the secretary of the association was appointed a committee to confer with the others named.

DR. M. M. HAMLIN, St. Louis, discussed interstate reciprocity and outlined the course pursued by the Missouri board.

Proposed Amendment.

Dr. J. R. GUTHRIE, Dean of the Medical Department of the University of Iowa, suggested that at the next annual meeting of the association the constitution be amended by striking out all reference to credits that may be allowed for work done in non-medical institutions, making attendance on four years of medical work in a medical college a requirement for graduation.

Amendments to Constitution.

By unanimous consent subsection (d) of Section 1, Article III, was amended to read as follows: "Certificates from reputable instructors recognized by the State Board of Medical Examiners duly authorized by law, or by the superintendent of public instruction in states having no examining board, may be accepted in lieu of any part of this examination."

Section 2 of Article III was amended to conform with the above by inserting after the words "under the authority of," the following: "the Board of Examiners or."

The next meeting of the association will be held in Richmond, Va., March 18, 1907.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting Held Feb. 14, 1906.

The President, DR. CHARLES K. MILLS, in the Chair.

DR. JOHN B. ROBERTS exhibited a dilated Meckel's diverticulum of the ileum which had caused strangulation of the intestine and obstruction.

Prognosis in Tuberculosis of the Lungs.

DR. JOSEPH WALSH said that prognosis must be viewed from two points: Absolute and practical cure. The latter viewpoint was especially considered. Primary factors in the prognosis of tuberculosis in regard to usefulness or practical cure are the amount of involvement, duration of disease, susceptibility to the toxin as manifested by rapid pulse, high temperature, and loss of weight, the dissemination and the association of complications. Secondary factors, which, however, in individual cases might become of prime importance, are age, sex, race, condition of life, intelligence, temperament, occupation or environment, and financial resources. Among the primary factors the amount of involvement is probably the least important. One patient with involvement of only one or two inches at the top of the lung, if other symptoms are severe, might die; while another patient with practically complete involvement of a whole lung, might recover so as to lead a useful life for an indefinite number of years. Marked toxic symptoms, such as rapid pulse, high temperature, and either rapid or considerable loss of weight, make the prognosis unfavorable. The reverse of this is likewise true. Under weight counts practically the same, or even a little more than loss of weight. Laryngeal tuberculosis has usually been considered of bad prognostic importance for the reason that laryngeal tuberculosis is a rare primary condition and usually occurs only in association with considerable lung involvement. Practically the same, Dr. Walsh thought, might he said of intestinal tuberculosis.

A previous history of tuberculosis of the cervical glands, tuberculosis of the lungs associated with fistula-in-ano, and a previous pleurisy gives a better prognosis. Complications on the part of the lungs themselves, the heart, the kidneys and the digestive tract rendered the prognosis less good.

The most critical age is the time between 15 and 25. The more remote the age on either side the better the prognosis. The better the environment in which the patient has been living, the worse the prognosis. The only remedy for the prevention or cure of tuberculosis is a regular life with sufficient rest, fresh air and good nourishment. If the patient has had these, and the tuberculosis has developed in spite of them, the susceptibility is so great that a cure is not likely. On the contrary a tuberculosis may have developed on account of bad environment and little nourishment, and such a patient's resistance may be good. If he is put under proper conditions, however, it usually happens that when a cure is

effected, for pecuniary reasons it is necessary to return to the old environment and the chances of a relapse are great. Consequently the worse the environment the better the prognosis, though the greater the likelihood of eventual relapse. The longer the patient has had the disease, other things being equal, the better the prognosis.

Roentgen Treatment of Some Non-Malignant Superficial Lesions.

DR. CHARLES LESTER LEONARD said that definite indications for employing the Roentgen rays have been determined in the treatment of superficial lesions; and that a dosage that is sufficiently accurate for comparison and for efficient employment is known. The most valuable treatment by this method is the post-operative, that is, in combination with early operation. He included among the superficial lesions those glandular organs that lie beneath the surface and spoke of the remarkable results that had been produced in tubercular and simple adenitis and the sinuses that often follow operation.

He reported four cases of goiter in which the treatment had been applied for its alterative action, and because of the analogous character of their structures to fibrous malignant disease, in which beneficial results had often been seen. One patient had remained cured for three years. It was a case of chronic, simple goiter of twenty years' standing. A second had remained cured eighteen months since treatment was stopped, with entire absence of nervous symptoms. A third patient, a case of exophthalmic goiter, was much improved, but discontinued treatment. A fourth patient is improving under treatment.

The depilatory action of the ray has been found of great value in syphilis, favus, ringworm and hypertrichosis. The stimulant action due to modification in dosage was illustrated by the beneficial action in alopecia areata. Lupus illustrated the several lesions that yield rapidly to this treatment, with a remarkable restoration of the normal, and without breaking down the tissues. He also reported a number of severe and chronic cases of eczemas and psoriasis, varying from seven to twenty years in duration, that yielded to this method of treatment. Another group of difficult cases amenable to this treatment are the discines. Here rapid results are obtained without scarring or disfigurement. Keloids, especially those that have taken on retrograde degeneration of a malignant type, are amenable to this method of treatment.

Exophthalmic Goiter Treated by the Roentgen Rays.

DR. G. E. PFAHLER and DR. M. C. THURSH reported the case of a young woman who had the nervous symptoms extending over a period of several months. Then the right lobe of the thyroid gland became enlarged. After the goiter had existed for two months x-ray treatment was begun. After twenty-two treatments extending over a period of two months she appeared to be well. Improvement was noticed after a month. She gained 25 pounds in weight, and the pulse fell from 120 to 72. The authors have collected thirty-one cases of goiter, including four of the exophthalmic type, treated by this method. Twenty-eight showed improvement.

Calomel in Eclampsia.

DR. W. REYNOLDS WILSON said that irritation of the kidneys begins early in pregnancy and imposes a task on the renal epithelium which makes the balance between the production of toxin and the compensatory elimination extremely precarious. The function of the liver goes hand in hand with that of the kidneys, and when the toxic ingredients of the blood remain unaffected by the converting function of the liver, the burden on the kidneys becomes too great and eclampsia is the result. The action of the bile as a preventive of intestinal fermentation hangs also on the efficiency of the liver function. Calomel is, therefore, indicated in the therapeutics of eclampsia, first, on account of its diuretic effect; second, on account of its hydragogue action, which aids in elimination; and third, on account of its corrective effect in the presence of intestinal fermentation. Ten, fifteen and twenty grains, given in the convulsive stage, while opportunity for medication is present, seem to have the best effect. Morphine, as an adjunct, is very important, although it is regarded by Dr. Wilson as an un-

desirable sedative in the presence of an old nephritis. Its use, however, is strongly urged on account of its action in combating the undesirable effect of calomel, as shown in salivation and undue purgation, although the latter effect of calomel is never to be taken into consideration as a disadvantage.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Cold in the Head.

In a case of ordinary cold in the head the best results are obtained, according to F. P. Atkinson in *British Med. Jour.*, by the following treatment:

R. Spts. etheris nitrosi		
Spts. ammon. arom. aa	5ss	2
Aque	3i	30

M. Sig.: To be taken at one dose and repeat in two hours, then once every four hours.

If there be a thick discharge from the nose the following is recommended as an insufflation:

R. Cocaine hydrochlor.	gr. i	106
Menthol	gr. ii	12
Acidi borici	gr. C	6/65

M. Sig.: A small amount to be used as an insufflation into the nares two or three times a day.

[Care should be taken to prevent the unauthorized refilling of this prescription.]

If the inflammation should extend to the trachea as shown by a tickling sensation in the throat when a deep breath is taken, Atkinson recommends the following combination:

R. Liq. ammon. acetat.	3ii	8
Spts. etheris nitrosi	gr. x	65
Aque	3i	30

M. Sig.: To be taken at one dose and repeat every four hours.

In the treatment of cold in the head or acute rhinitis, Ingals recommends daily sponging of the chest with cold water or salt water, bathing the feet every morning in cold water, as prophylactic measures, and the avoidance of sudden exposure, damp clothing and wet feet. In the beginning an attack may frequently be aborted by moderately large doses of opium, quinin or the ammonium salts. The following combination is recommended in the early stages of the disease:

R. Morphine sulph.	gr. 1/8	008
Atropine sulph.	gr. 1/20	0005
Puly. ipecac. comp.	gr. x	65
Quinine sulph.	gr. vi	40

M. Ft. cap. No. i. Sig.: One such capsule at bedtime, followed by a hot drink.

Preparations containing ammonium carbonate or ammonium chlorid combined with liquor ammonii acetatis are recommended by Ingals. He speaks of the advisability of reducing the amount of liquids to a minimum during the active course of the disease. The attack may be cut short by the administration of the spirits of camphor in 10-drop doses, administered on a lump of sugar, or potassium nitrate in 5-grain (.30) doses, or spirits etheris nitrosi in 20-minim (1.20) doses, or solution of ammonium acetate in 2-dram (8.00) doses, repeated from time to time.

Inspiration through the nose of warm vapors or sprays of mild solutions similar to the following are recommended:

R. Ammonii chloridi	gr. ii	12
Aque	3i	30

M. Sig.: As a spray for the nose. Or:

R. Acidi borici	gr. viii	40
Aque	3i	30

M. Sig.: To be used as a spray or wash to the nose.

Oil sprays should follow the use of these watery sprays as the oil is sedative in character.

Epilepsy.

In the treatment of epilepsy in a man 57 years of age who had suffered from the disease for fifty-two years, Matthew Woods, in *Med. Record*, recommended that the patient be placed on a vegetable diet, with a small amount of meat taken in the middle of the day. The supper consisted of tea or coffee, with bread and butter, avoiding such articles as cabbage, veal, pork, cooked tomatoes, pastry and other foods which were liable to undergo fermentation.

The following combination was ordered to be taken before each meal and at bedtime:

R. Puly. capsici	gr. 1/10	006
Strych. sulph.	gr. 1/30	002
Ferri hydrocyanatis	gr. 1/2	03

M. Ft. pillula No. i. Sig.: One before each meal and at bedtime.

The following was also prescribed:

R. Potassii bromidi	3iss	6i
---------------------	------	----

M. Ft. chart. No. iv. Sig.: One powder to be given at 8 a. m., 12 m., 4 p. m. and 8 p. m., well diluted with water.

The quantity of water was to be increased one ounce every week until each dose was taken in 12 ounces of water. When the attacks were nocturnal the last two doses were to be combined, taken at 9 o'clock in a pint of water.

Syphilis.

In the treatment of syphilis F. R. Sturgis, in his "Manual of Venereal Diseases," states that the initial lesion should not be cauterized unless it be attacked by phagedena when such a proceeding is admissible. When there are no complications, however, it may do harm. Mercury should not be used internally at this stage of the disease, as the appearance of the syphilide is retarded and the diagnosis rendered doubtful until several months have passed. Consequently no harm is done by withholding this treatment until ample time has been given for their appearance.

When the patient's appearance shows the presence of the syphilides, associated with mucous patches in the throat and on the tongue, alopecia, hemierania and glandular induration, mercury is indicated, and there is no preparation, according to Sturgis, which can act as a suitable substitute. During this period of papular eruption, therefore, the following combination is recommended:

R. Masse hydragryi	gr. ii	12
Ferri sulph. (exsiccated)	gr. i	06

M. Ft. pillula No. i. Sig.: From three to six such pills a day.

It is best to begin with one pill three times a day after meals, and to increase the number to two, three times a day.

The bichlorid of mercury is recommended by some authorities, administered as follows:

R. Hydragryvi bichloridi	gr. 1/50 to 1/10	0012-006
Saponis q. s.		

M. Sig.: One such pill after each meal.

If necessary to check the action of the mercury on the bowels, opium in doses of gr. 1/5 to 1/4 (.012-.015), may be added to each pill.

Mercury may be given in another form as follows:

R. Hydragryvi protoiodidi	gr. 1/5 to 1/12	012-03
Ext. gentiane	gr. i	06

M. Ft. pillula No. i. Sig.: One such pill three times a day.

This author prefers blue mass and iron pill on account of its efficacy and tolerance by the system.

The mercury should be continued until all the symptoms have disappeared or toxic conditions have arisen, such as diarrhea, sponginess of the gums and salivation. The last symptom should be avoided, if possible, so that the administration of mercury will not have to be stopped. If salivation should arise all the treatment should be suspended and the following combination prescribed:

R. Potassii chloratis	3i	4i
Aque	3vi	180

M. Sig.: To be used locally as a mouth wash, and internally in teaspoonful doses, four times a day.

The foregoing checks the sponginess of the gums, the fetor of the breath and the flow of saliva. Other preparations which perform similar service are the following:

R. Tinct. belladonnae.....3ii iv 8-15
Aque.....3ii 60

M. Sig.: One teaspoonful four times a day in water.

Atropin may be used in preference to belladonna as follows:

R. Atropinae sulph.....gr. 1-10 1006
Alcoholis.....3ss 15
Aque q. s. ad.....3ii 60

M. Sig.: One teaspoonful three or four times a day.

The potassium chlorate should be used as a mouth wash along with the internal use of the belladonna preparation.

If the sponginess is excessive and dropping out of the teeth is threatened, nitric acid is recommended as follows:

R. Acidi nitrici dil.....3iv 15
Aque.....3ii 60

M. Sig.: One teaspoonful four times a day in water.

As soon as the secondary symptoms have disappeared and no staining of the skin is left from the eruptions, the mercury should be discontinued in order not to create too great a tolerance by the system for the drug, and also to determine whether or not other lesions are about to follow. As the later stages of the disease are reached the mixed treatment should be substituted as follows, if it is decided to give the mercury internally:

R. Hydrargyri protoiodidi.....gr. ss-i 103-06
Ext. gentiane.....gr. i 106

M. Sig.: In one dose once daily, before lunch. And:

R. Potassii iodidi.....3ii 8
Tinct. cinchona comp.....gr. i 8
Tinct. gentiane, aa.....3ss 15
Aque q. s. ad.....3ii 60

M. Sig.: One teaspoonful well diluted in water, morning and evening, before meals.

The iodides may be administered in the form of a saturated solution well diluted in water, milk or Vichy water.

The mercury and iodid may be combined and given in the same mixture as follows:

R. Hydrarg. bichloridi.....gr. 1-4-i 015-06
Or
Hydrarg. biniodidi.....gr. 1-4-i 015-06
Potass. iodidi.....3ii 8
Tinct. gentiane.....3i 30
Aque, aa.....3i 30

M. Sig.: One teaspoonful well diluted in water twice a day, before meals.

The preparations are recommended, given before meals, to promote rapid absorption unless stomach and intestinal disturbances arise. If it is preferable for any reason to give mercury other than by the mouth it may be given in the form of an inunction or by means of mercurial vapor baths, or subcutaneously.

In order to avoid the dirty feeling produced by the greasy substances applied to the skin Sturgis recommends that the oleate of mercury be applied to the soles of the feet in from 10 to 20 per cent. strength. The patient should be directed to bathe the feet thoroughly in hot water on the night on which the first inunction is to be applied, then half a dram of the 20 per cent. oleate of mercury is rubbed briskly into the sole of the right foot, and this is repeated the following night on the left foot. The same stockings, which should be of wool, are worn night and day. The administration of iodid of potassium should be kept up continuously. If this preparation can not be borne the following combination is recommended:

R. Tinct. iodi.....3ss 15
Syr. aurantii q. s. ad.....3iv 120

M. Sig.: One teaspoonful well diluted in water, three times a day, before meals.

The foregoing dose should be increased in the same way as the potassium iodid.

The following statements are laid down by the author in considering the treatment of syphilis:

1. The average case of syphilis runs its course in from eighteen to twenty-four months.

2. Under proper and careful treatment the graver forms of syphilis seldom occur.

3. The patient should be observed occasionally for another eighteen months.

Why Mercury Is Contraindicated in Tuberculosis and Other Wasting Diseases.

PRESBURY writes for information concerning the statement in the special article on "The Pharmacopœia and the Physician," in Chapter VIII, Feb. 17, 1906, page 507, to the effect that the mercurials are contraindicated in chronic conditions.

A satisfactory answer to this question necessitates a brief statement of the pharmacologic action and consequent therapeutic uses of mercurial preparations. For a long time mercurials have been employed by the medical profession, and it seems that after many years of extensive use, knowledge on this subject should begin to crystallize, and it has, in a way. The crystals are not perfect and recrystallization will doubtlessly be repeated from time to time, but our knowledge concerning the action and value of mercurials in the treatment of disease is much more positive and exact than our knowledge of the great majority of medicaments prescribed daily by the most intelligent members of the profession.

The therapeutic uses of mercurials apparently approved by professional experience are as follows:

1. As a cathartic. We have been repeatedly told by physiologists and pharmacologists, who have experimented on animals with artificially established biliary fistulas, that mercury is not a cholagogue. Indeed, these scientific men tell us that there is not a real cholagogue in our whole list of therapeutic agents, and by this they mean that there is nothing which in safe doses at least will increase measurably the quantity of bile formed by the liver within a given time. This is probably true, and it is well that it is so, because if we possessed such an agent it would be capable of doing great harm, and it is difficult to conceive of conditions in which it would be of great service. What the practitioner means by a "cholagogue" is an agent which aids in the expulsion of bile from the gall bladder and gall ducts into the intestines, and in certain conditions the practitioner, from thousands and tens of thousands of practical observations, is convinced that he has such an agent in calomel and other mercurials. On this point the findings of the laboratory men have been contradictory to one another, or at least not uniform, but the intelligent physician knows that he frequently meets a condition which after all is best described by the term "biliousness," in which the mercurial cathartic gives him better results than anything else. In the second place, experience in this case confirmed by more scientific evidence, shows that the mercurials furnish good, in some conditions the best, antifermentative cathartics. Our profession has learned, by its mistakes, that the continued administration of mercurial cathartics is not free from danger, but it has with equal certainty established the fact that in single large or in broken doses calomel in properly selected cases gives better results than any other purgative.

2. The specific action of the mercurial preparations in syphilis is as well established as that of quinin in malaria. The evidence on this point is overwhelmingly convincing. Mercury, in whatever form or by whatever avenue administered combines with proteids, and the inference from its specific action in syphilis is that it has a selective effect on the virus of syphilis and the proteids of cells that have been altered by this virus. In non-syphilitics the continued administration of mercury leads to cellular degenerations and disintegration. This is shown conclusively by the characteristic calcareous deposits in the kidneys in chronic mercurial poisoning. So frequently has this condition been observed and so carefully has it been studied that a diagnosis of mercurial poisoning may be made from this finding alone. It is pathognomonic.

It follows from what has been said that mercurials in other chronic diseases than syphilis are cell poisons. In tuberculosis and other wasting non-syphilitic diseases the chief object in the adoption of any therapeutic measures is to feed the cells of the body and not to destroy them. It follows, therefore, that these diseases mercurials, at least their continued or frequent administration, is contraindicated.

In cases of coexistent syphilis and tuberculosis, mercury is not contraindicated. In cases of this kind the regular syphilitic treatment should be carried out. It will have a good

effect on the patient by relieving the cells from the necessity of contending with the syphilitic virus and will thus indirectly and for the time improve the tuberculous condition. Even tuberculous syphilitics, as well as the non-tuberculous, often gain markedly in flesh under mercurials.

Medicolegal

When Physician Can Not Testify as to Services.

The Supreme Court of Alabama says, in *Duggar vs. Pitts*, an action brought by the latter party against an executor to recover for professional services as a physician, where a rehearing was denied, that section 1794 of the Alabama Code of 1896 was intended to remove the ban of incompetency placed by the common law against parties of interest as witnesses, "except that no person having a pecuniary interest in the result of the suit or proceeding shall be allowed to testify against the party to whom his interest is opposed as to any transaction with or statement by the deceased person whose estate is interested in the result or proceeding." Can it be doubted for a moment that the testimony of the plaintiff as to the number of visits he made the deceased and what he did to relieve him, did not tend to fasten a liability on the estate of the deceased and to diminish the same, in view of the fact that the testimony of other witnesses as to the value of the plaintiff's services was hypothesized on the number of visits and character of the treatment? The court thinks not. It cites in support of its position the decision of the Texas Court of Civil Appeals under a similar statute, in the case of *Garwood vs. Schlichenmaier*, 25 Tex. Civ. App. 176, and the decision of the Supreme Court of New York in the case of *Ross vs. Ross*, 6 Hun, 182, which it says has been approvingly cited several times by said court. Nor does the court consider that the admission of the plaintiff's testimony was error without injury although there was much other evidence tending to establish his claim, and showing that he had treated the decedent faithfully and skillfully for a number of months. It says that, as above intimated, his was the only evidence fixing the number of visits, and while the evidence of other witnesses as to the value of services was partially based on facts independent of the plaintiff's testimony, yet the number of visits were considered in estimating the value of the plaintiff's services, which was not known to the witness whose evidence was partially hypothesized on the number of visits testified to by the plaintiff. And so it holds that the trial court erred in not sustaining the defendant's objections to questions to the plaintiff as to visits to the decedent, what he did for him, and how he relieved his suffering. It also holds that there was a failure to establish a predicate for the evidence of certain physicians as to the value of medical services in Selma, as each of them admitted that he did not know the customary charges in Selma and Dallas County.

Liability for Injury to Sick and Lame from Sidewalks.

The Supreme Court of Washington holds that in *Short vs. City of Spokane*, an action brought to recover damages for personal injuries on account of an alleged defective condition of a sidewalk, the following instruction should have been given the jury: The duty of caring and of abstaining from the unlawful injury of another applies to the sick, the weak, the infirm, as fully as to the strong and healthy; and when the duty is violated the measure of damages is for the injury done, even though injury might not have resulted but for the peculiar physical condition of the person injured, or may have been augmented thereby. The proximate cause of an injury is the efficient cause. The public streets and sidewalks in a city are not constructed and maintained for the sole use of the healthy and robust people, but for the use of the infirm, the sick and decrepit as well. They may be lawfully traveled by every citizen, without regard to age, sex or physical condition. If the city negligently permit the streets and sidewalks to remain out of repair, and any person (who is himself free from negligence) is injured, the city is liable for the injury. The city is chargeable with the knowledge that people

of different bodily conditions travel its streets, and that among these are the weak, the decrepit and those with organic predisposition to disease. The city is chargeable with knowledge that all classes of persons, including both the healthy, and diseased, and lame, constantly travel its streets and sidewalks, and that such disease or lameness might greatly aggravate a bodily injury. Hence the city has reasonable ground to expect that if one of that class, who are diseased or lame, is injured by reason of a defect in the sidewalk or street, the disease or lameness might develop and retard or prevent a cure.

Giving "Light Treatments," Etc., Practice of Medicine.

The Supreme Court of Tennessee says that the facts presented on the trial of the case of *O'Neil vs. State* were practically undisputed and embraced the following salient points: The first-named party, who was the defendant in the court, below, charged with practicing medicine without a license, opened up an office with all the arrangements necessary for the treatment of his patients. According to the testimony, he would first subject his patients to a careful examination, including a microscopic test of a drop of blood taken from some part of the patient's body. He would then determine, from his diagnosis, the nature of the patient's ailment and whether or not it would require his treatment. It was shown in the record that the method of treatment was practically uniform in all cases. "The patient is denuded of clothing and placed in a closed cabinet, and his body is thereon subjected to the rays of two large electric arc lights, one being located in front of his body and one at the back. This treatment is continued for about thirty minutes at each sitting, and then the patient, who is by this time in a profuse perspiration, is taken into another room and rubbed off, after which he goes about his business. In addition to this general treatment a local application of the rays to the parts specially affected is made in some cases." In addition to prescribing the light treatment as the means of treatment for his patients, he gave medicines of various kinds, kept an account at a drug store where medicines were purchased, gave prescriptions in the form of orders on a certain store, advised several of his patients to take certain patent medicines as an auxiliary to his treatment, and was addressed and known as Dr. O'Neil. The record showed further that he was accustomed to make a uniform charge of \$100 in each case, for the application of the light treatment, but made no charge for medicines prescribed; hence he claimed that prescriptions were no part of his treatment.

The principal contentions of the defendant were: 1. That his professional business was not within the purview of the statute regulating the practice of medicine and surgery, for the reason that he was an optician within one of the two recognized definitions of that term, and was, therefore, expressly excepted from the operation of the statute. 2. Conceding that his business was comprehended by the statute, as applied to him, said statute was unconstitutional for two reasons: First, His method of practice was not such as it was within the power of the legislature to regulate, restrict or prohibit; second, the regulation and requirements of the act, as applied to his methods of practice, were arbitrary and unjust, because his business did not require the qualifications prescribed by the statute for those undertaking to practice medicine and surgery. But the Supreme Court is of the opinion that he was properly convicted of practicing medicine and surgery without having first procured a certificate of license from the State Board of Medical Examiners, as required by the act of 1901. It suggests that the definition of "optician" ordinarily understood should be given that word in the statute. Moreover, as the proof showed that the defendant made a microscopic examination of the blood in his diagnosis of disease, and also wrote prescriptions and prescribed remedies, although it must be admitted that his principal mode of treatment was by what he denominated the "functional ray," he could not claim exemption as an optician even under the very technical definition of the word which he invoked. But the determinative fact against him on the record was that he was holding himself out to the world as a practitioner of the healing arts and was soliciting patients afflicted with disease for treatment.

- 2 *Gonorrhea in Women. P. Findley, Omaha, Neb.
- 3 *Foreign Bodies in the Bronchi. T. A. Clayton, Washington, D. C.
- 4 *Actinomycosis Limited to the Urinary Tract. E. MacD. Stanton, Chicago.
- 5 Pyrexia, with the Report of a Case in Which Autopsy Revealed Toxemia Rather than Pyemia. D. C. Peyton, Jeffersonville, Ind.
- 6 Hand Disinfection. C. P. Obendorf, New York.

1. **No Yellow Fever Without Mosquitoes.**—Carroll argues that the logical conclusion from the investigations which have been made would seem to be that the parasite of yellow fever belongs to the animal kingdom for the following reasons: 1. It is absolutely necessary for its continued existence that it pass alternately through man and the mosquito, and its parasitic existence in these hosts is obligatory. 2. The fact that a period of about two weeks must elapse before the contaminated mosquito is capable of infecting, points to a definite cycle of development in that insect. 3. The limitation of its development cycle to mosquitoes of a single genus and to a single vertebrate conforms to a natural zoologic law and does not agree with our present knowledge of the life history of bacteria. 4. The effects of climate and temperature on the stegetomyia and on the rate of development of the yellow fever parasite within the body of the insect are exactly the same as the effects of the same conditions on the anopheles mosquito and the malarial parasite.

2. **Gonorrhea in Women.**—Findley says that the anatomic recognition of gonorrhea of the urogenital tract may be impossible, particularly in cases of long standing. For this reason the diagnosis must occasionally rest on the finding of an inflammatory lesion in one or more portions of the tract, and associating these lesions with a history of exposure to gonorrheal infection. A diagnosis that admits of no doubt can only be based on the finding of the gonococcus in the secretions or tissues. The small size of gonococci and their scarcity in the tissues in chronic cases may necessitate the microscopic examination of a large number of sections. Since the cure of gonorrhea is so unsatisfactory, and when deeply seated is usually only accomplished by a mutilating operation which too often unsexes the woman, prophylaxis becomes the paramount issue in the management of gonorrhea in women. Unfortunately, it is not alone the laity which is in need of education in this respect; the profession is often guilty of being too hasty in pronouncing a cure and in giving sanction to marriage or to the resumption of the marital relation. Untimely interference with uterine and urethral applications in the early stage of the disease too often causes an extension of the infection and makes a serious lesion of what might otherwise have been a self-limiting disease.

3. **Foreign Bodies in Bronchi.**—Clayton tabulates 50 cases not heretofore brought together. Among these 38 patients recovered and 12 died, a death rate of 24 per cent. Of 33 patients operated on 28 recovered and 5 died, while of 17 not operated on 10 recovered and 7 died.

4. **Actinomycosis Limited to Urinary Tract.**—Stanton records a case which was clinically one of cystitis and pyelonephritis, the actinomycotic character of the kidney lesions not being recognized during life or at the time of autopsy, but being discovered only on histologic examination of the kidney and bladder.

8. **Fever in Tertiary Syphilis.**—Carpenter calls attention to the difficulty in the diagnosis of fever in tertiary syphilis. He illustrates this point by giving the histories of two cases recently observed, which show the necessity of administering mercury with caution. Both the patients whose histories are reported improved more rapidly when potassium iodid was used alone.

9. **Diet in Typhoid.**—Clayton's treatment of a case of typhoid fever, no matter on what day of the disease it may come under his care, is as follows: The regulation six ounces of milk are given every two hours, night and day, while the patient is awake. In place of milk, in order to vary the monotony for those who can take milk, and as a substitute for those who can not, animal broths are given. After the subsidence of the more acute symptoms the patient is asked if he is hungry, and if he applies in the affirmative a soft-boiled or poached egg is allowed, and if well borne the number is gradually increased to three or more a day. Jelly or blanc mange, custard, soft toast, the soft part of baked apple, and rice which has been boiled four hours, are the next additions. After this scraped beef or chop, very finely divided chicken, and baked potato are tried. Clayton does not advocate so full a diet in every case, for each patient must be carefully studied as an individual. He believes that most of the foods mentioned are quite as digestible, far more palatable, and rather less likely to cause perforation or hemorrhage by their local action, or gas production, than milk.

10. **Curability of Tuberculosis.**—Langhorst considers that the keynote of success is an early diagnosis, tonics and rest. Proper therapeutic and hygienic modalities directed against the disease will so reinforce Nature as to make the conquest an easy one.

11. **Treatment of Urethral Stricture.**—Muren advocates the treatment of stricture by gradual dilatation. In men beyond middle age the anterior urethra should be thoroughly flushed before any instrumentation. The best lubricant for urethral instruments is made from Irish moss, and contains a small percentage of formalin. Muren has been more successful in filling the urethra with a number of straight instruments, successively attempting the passage of each, than in the use of instruments with variously twisted ends. He instructs his stricture patients with healthy bladders to hold the urine for a couple of hours before treatment. Voided immediately after dilatation it irrigates the urethra without discomfort.

13. **Displacement of the Fallopian Tubes to Produce Sterility.**—Rockey mentions instances in which he considers an abortion justifiable as a necessity in saving life, and others in which the possible occurrence of pregnancy would expose the patient to danger which it is most desirable to avoid. His technic is as follows: When the cornu of the uterus is brought into the field of incision, the tube is seized near its uterine end with a pair of forceps. The sharp point of a pair of scissors is thrust into the cornu, and the uterine end of the tube is cut out by a V-shaped incision with two cuts of the scissors. The wedge-shaped point of the excised end of the tube is caught with the forceps, drawn out a little between the partly closed blades of the scissors and cut off. The severed end of the tube will then slip into the peritoneal sheath and be completely covered by it. One catgut suture is passed through this cut, then through the fundus posterior to the inner end of the V-shaped incision from behind, forward, and tied, thus fastening the closed ends of the tube back of its original position. Two more sutures are passed around the tube and through the cornu to close the V, to control the bleeding, and to fasten the tube to the outside of the closed cornu.

16. **Acute Articular Rheumatism.**—Cole reports a case of polyarthritis of mild grade with marked effusion into only one joint, with streptococci cultivated from this joint, and rapid and complete recovery. Other cases are also reported to demonstrate that streptococci may induce a polyarthritis of very moderate grade. Cole thinks that there is one fact which seems to point to streptococci or some very closely related organisms as the cause of rheumatic fever. There are several diseases in which one attack predisposes to another; instead of immunity there follows heightened susceptibility. Among these diseases are erysipelas, tonsillitis, pneumonia and rheumatism. The very close relation of pneumococcus to streptococcus is now well recognized. While probably of no special value in arriving at a definite conclusion, this association of these four diseases is of interest.

Cole thinks that there are three possibilities: First, that acute articular rheumatism is a definite, specific, infectious disease, the cause of which we do not know, and that the cocci which have been isolated were secondary invaders. Second, that there is no such specific disease as acute articular rheumatism, but that the cases grouped under this term are those mild and moderately severe cases of general streptococcal infection in which the joints and heart are generally involved. Third, that acute articular rheumatism is due to a special form of streptococcus, which at present we have no accurate method of distinguishing from *Streptococcus pyogenes*, but which, owing to the specific character of the lesions induced in man, must possess special characteristics.

28. **Congenital Dislocation of the Hip Joint.**—Thienhaus claims that congenital dislocation of the hip joint is as present perfectly curable in from 60 to 80 per cent. of all cases treated within the time limit by so-called bloodless or bloody methods. The best time for treatment is from the second to the fifth year. Patients over 8 years of age should only be subjected to a trial of reduction when examination has shown that the shortening of muscles, blood vessels and nerves is not so extensive as to make serious injuries inevitable, and that malposition exists between the head of the femur and the acetabulum. The bloodless methods of reduction should be tried first, and only after two or three attempts have been made without success or with bad functional results should the bloody methods be resorted to.

29. **Retrospectus: A. D. 2061.**—Strobbach's paper is an essay on sanitation, with comparisons of conditions existing in the beginning of the twentieth century with those existing in the year 2061. At that time medical colleges are owned and controlled by the government. State examining boards have been abolished. The President's cabinet numbers among its members a secretary of health who is not a physician, but a man who has studied sanitation and is conversant with the subject and its needs. He is responsible to the President. At the head of the army and responsible to the secretary is the chief sanitarian, a man who has risen from the ranks of the army, receiving promotion only by competitive examination and meritorious service. Uniformity reigns everywhere. Utopia has arrived. There is nothing left to be wished for.

36. **Leucocytosis in Surgery.**—Clifton believes that the significance of leucocytosis in surgery, particularly in abdominal surgery, is not sufficiently appreciated. He says that if the leucocytes are counted frequently and the count weighed carefully as only one symptom of many, it may be of great value, but that a single count is not valuable for any serious decision. In patients requiring operation the objection to this measure is that several counts may be necessary for a decisive result and that this may delay intervention too long.

37. **Address.**—Takaki discusses beriberi and the Japanese medical schools.

48. **Aneurisms.**—Parham reports two cases, one a case of popliteal aneurism treated by intra-aneurismal suture of the vessel orifices according to the method of Matas, and the other an aneurism involving the second and third portions of the left subclavian artery, beginning just behind the scalenus muscle and extending to the point of disappearance of the artery under the clavicle. The inner three-fourths of the clavicle were resected. The first portion of the artery just inside the scalenus muscle was ligated and the sac was incised. This was followed by severe hemorrhage which was finally controlled by suture of the proximal opening within the sac and distal ligation of the subclavian artery. Parham states that the operative indications for this procedure are: 1. The practicability of laying open and inspecting the interior of the sac. 2. The possibility of applying a constrictor, clamp or temporary ligature to the proximal side of the tumor. In the second case reported the suture was employed because proximal ligation failed to stop the bleeding completely. The operation of suture within the sac is to be preferred to ligation, because: 1. Every possible bit of artery is saved, except that actually forming the sac of the aneurism. 2. Suture accomplishes simple approximation of the intima, and does not cut

knowledge as best he may, and a large part of it he obtains from the advertising literature of the proprietary-medicine manufacturer.

69. **Retina and Circulatory System.**—Woodruff states that with the ophthalmoscope many a commencing general vascular degeneration can be detected in its incipency by noting the alterations in the retina and in the retinal circulation. A man apparently in good health, exhibiting no symptoms of disease apart from a slight defect in vision, may be the subject of vascular changes of the most serious character. Woodruff advises that the internist familiarize himself with the use of the ophthalmoscope and the normal appearance of the background of the eye. Negative evidence is often quite as valuable as positive. When no signs of capillary alterations are to be found in the retinal arteries, nor changes in the retina itself, the probability is that there are no advancing changes going on in the vessels elsewhere. When structural changes in the retina are found it is positive evidence that these are only a part of a fibrosis more or less extensive in the arteries and capillaries throughout the whole system. The retinal vessels possess no anastomoses but are terminal vessels, and for this reason the region which depends for its nutrition on these vessels is liable to show alterations in structure that are a reflection of widespread vascular degeneration.

- 78 Neglected Means for the Prevention of Disease. A. W. Dunning, St. Paul.

75. **Treatment of Syphilitic Cicatrices in the Mouth.**—The plan of treatment described by Schade consists of the construction of a suitable device to be worn continuously by the patient with a view to keep apart permanently the opposing surfaces of the velum palati and the postpharyngeal wall. The apparatus, preferably made of vulcanite, ought not to be introduced in recent cases until the acute symptoms of inflammation and tissue necrosis have subsided under appropriate local and constitutional treatment. In old chronic cases in which either partial or total adhesions exist and no inflammation or ulceration is present, the device should be employed immediately after complete detachment of the adherent soft palate. The device is composed of an obturator and a palatine plate which is designed to hold the obturator firmly in place by means of metallic dentary clasps. The intermediary operation and the details for making the obturator are described in detail.

- 85 Treatment of Rheumatism. J. W. Carey, Whitesboro.
- 86 Conditions Existing Between Physician and Druggist. J. M. Martin, Illinois.

80. **Periculous Malarial Fever.**—Crosthwait reports four cases of periculous malarial fever, one an example of the comatose form, a second illustrating the algid variety, and two cases of hemorrhage. In one of the hemorrhagic cases there appeared during the course of an attack of remittent malarial

fever a most alarming case of hemorrhage, profuse nose bleeding, hemoptysis, hemorrhages from the buccal membrane and from the bowels. The hemorrhages were controlled, but reappeared promptly on the administration of quinin. The second case of hemorrhage was one of quinin hemoglobinuria. The patient died, not from the effects of the hemoglobinuria *per se*, but from the complex result of quinin poisoning and uremia.

82. **Cure for Nasal Catarrh.**—Torbett calls his treatment divergent hydropathic gymnastics or massage. He devised the method for the purpose of training the capillary circulation to maintain an equilibrium in the mucous membrane and skin to resist the effects of sudden change in the temperature. A dairy thermometer, a glass nasal douche and two glasses are needed. To one glass of warm water, at a temperature of 98 F., one-half teaspoonful of bicarbonate of soda is added. To the second glass of water, at a temperature of 96 F., the same amount of sodium chlorid is added. The patient is shown how to use the douche with the soda solution in the mouth, also as a gargle and over the face, to be followed immediately by the colder salt solution. This should be used at least once daily for from three to six days, when the soda solution should be raised one degree and the salt solution lowered one degree until the soda solution is from 115 to 120 F., while the salt solution is down to 75 or 80 F. The face, neck and arms should be bathed with cold water every morning, and the entire body given divergent temperature baths at least once a week. The ordinary precautions as to diet and personal hygiene must also be observed.

- 90 Evils and Abuses of So-called Lodge Practice. P. J. Calvy, North Fond du Lac.
- 91 Pneumonia. P. L. Scanlan, Prairie du Chien.

87. **Appendicitis.**—Walbridge states that it is impossible to predict, with any degree of certainty, the outcome of an acute attack of appendicitis in any stage of the disease, no matter how mild the symptoms. He treats every acute appendicitis as an emergency case and operates at once, night or day, if the opportunity is offered early.

89. **Chronic Appendicitis and Neurasthenic Conditions.**—Prince is fully convinced that chronic appendiceal disease is responsible for a not inconsiderable percentage of cases of so-called neurasthenia, ranging from ordinary crankiness through nervous prostration and hysteria to actual insanity. Three cases are reported illustrating a number of factors bearing on this subject.

- 102 *Four Cases of Prostatic Obstruction. W. T. Bellfield, Chicago.

98. Medical Library.—In this paper Black discusses the function and scope of a medical library owned and controlled by a county medical society; the relation of the medical library to the community at large; the growth of the library and how it can be made an active agency for good in the daily work of the physician.

102. Prostatic Obstruction.—Belfield reports four cases. The first patient suffered from sclerosis of the gland, which was treated by channeling a canal through the fibrous vesical orifice by means of the galvanic cautery introduced through a median perineal urethrotomy. The second patient had a hypertrophy of the prostate. A large middle lobe and two lateral outgrowths were removed by the same median perineal urethrotomy performed for galvano-prostatotomy in the first case. The third patient, the victim of carcinoma, was treated in a manner different from the usual custom followed in these cases. A simple puncture was made with a small trocar and canula and a small soft catheter was then introduced through the canula, which was withdrawn, leaving the catheter to drain the bladder. After three or four days the catheter was removed, cleansed and reintroduced through the fistulous tract. Thereafter the catheter is removed and cleansed daily and the bladder washed out by the patient himself. Belfield advises inspecting the vesical interior to determine the presence of calculi. If the cystoscope can not be introduced through the prostatic urethra, a straight cystoscope can be introduced through the suprapubic canula at the time the puncture is made.

The fourth patient illustrates two of the common evils of perineal prostatectomy, viz., a permanent perineal fistula and permanent incontinence of urine. Belfield says that this operation, the removal of the prostate through its posterior surface, should be generally abandoned. He mentions three operations for the removal of prostatic obstruction: 1, galvano-prostatotomy for channeling a fibrous prostate; 2, enucleation of adenomatous masses from the mucous surface either (a) through a median perineal urethrotomy or (b) through a suprapubic incision, the former when the growths can be reached on the perineum, otherwise the latter. The suprapubic incision is best made in two stages—the first incision extending, but not through, the bladder; four or five days later the second incision—through the bladder—is made, and the prostatic masses are enucleated. In this way the chief danger of a suprapubic operation—septic infection of the suprapubic sac—is minimized.

Present Methods in the Treatment of Pulmonary Tuberculosis. F. A. Johnson, Greenville.

4. Vaginal and Uterine Prolapse.—According to Carstens, apse is rare in nulliparae. If due to subinvolution and seen if it can often be relieved by supports, with local and constitutional treatment. If due to lacerations, these can be freed by plastic operations, but the mucous membrane must be reserved in women of child-bearing age. If there is pelvic bleeding these operations must be amplified by abdominal section. Carstens believes that an Alexander operation is indicated only in very rare cases, but when the abdomen must be opened on account of other conditions it is best to make one large intra-abdominal shortening of the round ligaments and kind of ventral suspension. In older patients, those of the menopause, a plastic operation is of no avail. A vaginectomy will be less dangerous and gives better relief on abdominal suspension.

120 Contamination of Water Supplies. N. K. Foster, Sacramento.

115. Etiology and Treatment of Chronic Bronchitis.—Perry attributes this form of bronchitis to a local edema of the bronchial mucous membranes. His treatment consists of the restriction of liquids to a proper proportion with the liquids excreted. The principle is to diminish the water in the body in the hope that any local accumulation in excess will also decrease. The chlorid of sodium in the food must be greatly reduced. Perry has treated twenty cases in the last three years according to this method, with good results. The treatment is best suited to patients with a rather abundant whitish viscid mucus, which is expectorated with difficulty, and who have some dyspnea and uneasy rest at night, with a cough.

British Medical Journal.

March 3.

- 1 *Recent Surgical Methods in the Treatment of Certain Forms of Paralysis. A. H. Tubby.
- 2 A Case of Myxedema. T. Fraser.
- 3 *The Borderland of Insanity. G. H. Savage.
- 4 Treatment of Neurosthenia. G. Rankin.
- 5 Neurosthenia, Degeneracy and Mobile Organs. P. C. Smith.
- 6 *Pathology of Epilepsy. J. Turner.

1. **Surgical Treatment of Paralysis.**—The types of cases discussed by Tubby are those arising from anterior poliomyelitis, spastic paralysis, ischemic paralysis and some traumatic lesions of the nerves. The modern methods of treatment discussed are tendon and muscle transplantation, arthrodesis and nerve anastomosis. Among the cases reported by Tubby are the following: Grafting the extensor proprius pollicis into the tibialis anticus, and part of the extensor longus digitorum into the internal cuneiform bone for paralytic equino-valgus associated with paralysis of the tibialis anticus; partial paralysis of the extensor cruris; insertion of the ilio-tibial band into the patella, which was followed by complete recovery of the power of extension of the leg; grafting the distal facial trunk for traumatic facial paralysis into the hypoglossal.

3. **Borderland of Insanity.**—Savage shows that there are persons who are nervously or mentally disordered, but who are not to be considered or treated as lunatics. He pleads for a much greater freedom for the treatment of the insane who are not dangerous to themselves or to society by physicians in general practice, and urges the utility of having some system of notifications as well as of certification. For some patients greater control is needed, while in others much more freedom and a natural return to a simpler life is to be preached—a real consistent simple life, with plainer food and more regular occupation.

6. **Pathology of Epilepsy.**—Taken together, that is, the correlation of the defectively developed and probably unstable nerve cells, with the local status of the blood stream resulting from intravascular clotting, Turner submits are the conditions which constitute the pathologic basis of an epileptic fit. On the part of the nerve cells the most important changes are: (a) A form indicative of imperfect development; (b) retention of subcortical nerve cells, also an indication of imperfect development; (c) either an acute form of cell change, similar to that produced by ligature of the cerebral arteries in a dog, or (d) groups of darkly stained, shrunken cells, representing a more chronic change, and very likely, at all events in some cases, the sequel of that just described. On the part of the vascular system: (e) Large numbers of blood plates in the blood; (f) different forms of intravascular clotting, probably in large measure derived from amalgamation of the blood plates, but to some extent also probably due to destruction of red blood corpuscles; (g) small cortical hemorrhages, which in some cases can be traced to rupture of a vessel blocked up by the aforementioned clot.

8. **Gastric Surgery.**—In this paper Paterson discusses perforation of a gastric ulcer, infantile hypertrophic stenosis of the pylorus and its treatment, the surgical treatment of cancer of the stomach, and the results, immediate and remote, of gastrectomy.

11. **Production of Ultra-Violet Rays.**—In order to overcome some of the objections to the present method of producing ultra-violet rays, Bowie employs various tubes and apparatus of glass and other materials. Of glass tubes he found one 9 inches long by 3 in diameter, gradually tapering toward one extremity, very suitable for general purposes. The end is fitted with a metallic cap, to which is fitted the terminal, and passing inward to a distance of one-third of the tube is the electrode, to end in the internal cathode (also anti-cathode). The latter is a disc of iron, and although other metals may be employed he has obtained the best results by using iron. In this form the body of the tube is encased in a metallic cylinder—the external anti-cathode (also cathode) which likewise carries its terminal. Interposed between the cylinder and tube is a porous material which can be kept cool for the purpose of absorbing any heat. On account of the small amount of heat rays present the free end of the tube may be fitted with a lens or lenses for concentrating the rays. The vacuum tube is connected with the secondary helix of the machine and can be approximated by a screw to the primary helix.

The working of the tube is as follows: Previous to turning on the current the secondary helix is placed at its furthest point from the primary and the condenser of the machine is raised so that the machine is working at its lowest capacity. The current is turned on and the tube glows. So sensitive is the tube that when *in situ*, and placed 12 feet from another machine which is working, the tube glows by induction. To obtain the greatest volume of ultra-violet rays the secondary helix is gradually approached towards the primary one, while the condenser is lowered to its greatest depth or capacity. The tube glows with great intensity and silently. From the internal cathode (also anti-cathode) is seen a corona of luminous points, while more distant from the corona it assumes pale violet or whitish-blue color which occupies the whole tube. These are the ordinary cathode and anti-cathode rays of Leard. Directly through the glass of the free end of the tube emerge the invisible ultra-violet rays. This radiation answers to all the known tests for ultra-violet rays. The tube when in use can be held in the hand or adjusted to a stand. When the tube is worked with high tension, it also takes the place of a rectifier and can be handled with safety. This is of considerable importance when the ordinary x-rays are wanted, although it has to be noted that much better results can be obtained the employment of low tension.

13. **Psychology of the Tuberculous.**—Gubb states that there are presumably two principles of morbid process at work in determining the psychological changes which take place in the tuberculous, and they require to be distinguished from each other, though clinically it can not always be possible to establish the distinction in the absence of the anatomic proof. There are (1) changes of mental temperament presumably due to the action on the nervous system of the toxins elaborated by the tubercle bacillus; and (2) modifications of character to mechanical interference with the cerebral functions secondary to the deposit of tubercle within or on the brain. The characteristic feature of the general psychology of the tuberculous is instability, feverish activity followed by periods of intense depression, phases of despair giving place to the elation of plans for a distant future, fits of hypochondria, from which is sought in intense application to work, a less indulgence in sensual pleasures and exaggerated idealism with a tendency to sentimentality and generalization. During the stage of invasion a certain tendency to refinement is noticeable, both physical and mental, and under its influence artistic and imaginative faculties are often stimulated to unprecedented feats, doomed but too often to failure by a collapse of physical energy.

The tendency to take a sanguine view of things becomes more marked as the disease advances. When a patient learns that his lungs are affected he usually displays anxiety and is depressed. The mental depression, however, gradually subsides until at the terminal period, in spite of overwhelming evidence that his days are numbered, the patient obstinately makes plans or initiates enterprises incapable of achievement in the brief space of life that remains. Per-

are buoyed up by a hope that knows no contradiction and display impatience or even anger when attempts are made to get them to realize the seriousness of their plight.

14. Inguinal Hernia in Boyhood.—The operation performed by Owen is a good deal like that of Mitchell-Banks, except that when passes the sutures deeply through Poupart's ligament and the muscular inner wall of the inguinal canal so as to ring them and keep them in permanent contact. The stitches cause the deposit of a large amount of plastic exudation, which in due course becomes fibrous tissue and makes a splendid barrier.

19. Etiology of Gout.—Hall reviews the causes of gout, but does not offer any new theories.

22. The Skeleton in Case of Undescended Testicles.—The patient in question is a man of 56 with empty, rudimentary scrotum. A testicle no larger than a grain of corn can be palpated in the right inguinal canal. A careful radiographic study was made of the different bones of this natural scrotum, calling the persistence of the epiphysal cartilages. The dow cast by the bones was like that of a child. The great chanter had been fractured at one time, probably from device ossification of the epiphysal cartilage. The long bones longer than correspond to the height, and other special features of the skeleton corroborate the assumptions of Ansel Bouin in regard to the results of defective functioning of interstitial gland of the testicle. (Their study of what we call "diastematic insufficiency" was summarized recently in these columns on page 690.)

3. Crushing Stones in Bile Duct.—Ombredanne has been making the 53 cases on record in which a gallstone in the main bile duct was crushed *in situ*. In 10 of the cases the attempted lithotripsy proved impracticable. Ombredanne has learned the operation successfully once and reports another published case. In 5 other cases on record the stone was crushed to facilitate its removal, but with success in only 3. Experience shows that, as a rule, the forceps fail when the stones cannot be crushed with the fingers; the hardness of gallstone is thus the principal point in the lithotripsy. In 10 of the 39 cases in which the stone was effectually crushed symptoms of retention of bile ceased at once. When contraindications are favorable, choledocholithotripsy is a simple, mild and effectual procedure. If the stone does not crumble easily between the fingers the attempt to crush it should be abandoned. This procedure should not be attempted unless the stone is single and of moderate size, the walls of the duct intact, or in cases in which conditions are not promising for bile drainage.

Appendicitis and Typhoid Fever.—Perrone describes 3 cases of appendicitis during or following typhoid fever, the etiologic anatomic findings demonstrating that the appendix is liable to be the seat of true typhoid lesions, and also that any appendicitis is liable to develop in the course of organic convalescence from typhoid fever. Dieulafoy calls this

latter form "paratyphoid appendicitis," and Perrone's experience indicates that it is much more frequent than generally supposed, and may run its course unrecognized. The prognosis of this form of appendicitis, if operated on in time, is far better than that of typhoid perforation. The serious condition of the patient is no contraindication to an operation, although in the severer cases local should be preferred to general anesthesia.

27. Essential Fragility of the Bones.—Broca describes the cases of two children. One had six fractures and one seven, occurring from slight falls at various intervals; the bone healed readily and rapidly with perfect consolidation. Two other cases of this essential fragility of the bones are also related. The patients were sisters, about 20 years old. One had fractured her leg or arm ten times between the ages of 5 and 16, the other eleven times before she was 12. These two patients seem to have outgrown the tendency to fractures. They took calcium phosphate and cod liver oil systematically, with special regard to hygiene, and are now apparently in good health, although the shadows in radiography seem less dense than that of normal bone.

31. Experiences with Mammary Cancer.—Summaries of the histories of 186 patients with mammary cancer operated on at von Hacker's clinic and followed to date are given, and various special points are emphasized. The total number of cases was 286. The proportion of married women (about 73 per cent.) is about that noted by other observers. Half the women had borne children, the average was four births. In only 4 cases was there a history of preceding mastitis in the breast affected, and in 1 of chronic eczema of the nipple. Trauma was blamed by the patients in nearly 10 per cent. of the cases. The lump had been first noticed at an average of nearly fifteen months before the operation, the intervals ranging from one month (10 cases) to one year (27 cases), and to ten years (1 case). Nineteen of the patients are still alive, in good health, and 4 died from an intercurrent disease after three years of health. Local recurrence was observed in 81 cases (43.54 per cent.) and 54 patients succumbed to metastasis (28.92 per cent.). In 27 cases recurrence was not observed until after an interval of from three to six and one-half years. There were nine tardy recurrences in each hundred cases of recurrence. The recurrence was operated on in 23 cases, the interval being from one month in one instance up to six and one-half years. Out of the 36 cases in which the supraclavicular glands were found already affected, 2 of the patients lived nearly four and five years, and 2 others are still alive, although 1 presents recurrence. Omitting these supraclavicular cases as practically inoperable, the proportion of permanent cures has been 25 in 150 cases (16.66 per cent.). The technique was that of Kötter and Halsted as a rule. Four patients succumbed to heart failure during or soon after the operation, 12 to pneumonia, 2 to marasmus, and 1 each to sepsis and erysipelas.

32. Compression of a Nerve.—Van Lier reports a case of median paralysis cured by an operation which removed a tumor pressing on the nerve. The case shows that a nerve trunk which had lost its conducting power by pressure from some connective-tissue formation or a callus, is able to regain it as soon as the pressure is removed. The patient was a man of 27 with median paralysis resulting from the pressure of an arterial hematoma which had developed after he had cut himself in the arm two weeks before the operation was undertaken. The nerve was found flattened to a ribbon by the pressure, but it gradually regained its function so that the motor function of the hand became normal. The sensory functions have not returned during the 2 years since. Van Lier reviews the various communications that have been published bearing on this subject of compression of the nerves, and describes some experiments with frogs.

36. Passive Congestion in Acute Inflammations.—Von Brunn reports the details of 65 cases of acute inflammations treated by Bier's method of passive congestion or congestive hyperemia. The verdict is very favorable on the whole, but as the method is so young he urges publication of the mishaps and failures with it as possibly liable to prove more instructive than the successes. He states that it is best to allow as wide a space as possible between the lesion and the constricting band, which Bier also emphasizes.

43. Iodin in Treatment of Cerebrospinal Meningitis.—Edelfsen advocates the use of iodic acid and its sodium salt (sodium iodate) rather than the halid salts of iodine in treatment of cerebrospinal meningitis and in all cases in which energetic action by iodine is desired. In his experience it prevented the development of serious sequelae of meningitis. He supplements it by application of ice to the back of the neck as well as to the head, and he also gives potassium bromid in large doses to control the cramps and the tendency to vomit. Lumbar puncture and injections with silver salts are also useful adjuvants, he states. The sodium iodate, he declares, has also done good service in cases of chronic glandular enlargement.

45. X-Ray Examination of the Stomach.—Holzknecht is privat docent of medical radiology at Vienna and radiologic expert to the Austrian courts. In his x-ray work on the stomach he has come to the conclusion that the truly normal stomach is small and has the pylorus at the lowest point. He remarks that this is the way an engineer would build the stomach to perform its functions properly. Very few persons, however, have this normal type of stomach. The majority of mankind, even persons entirely free from any gastric disturbances, have distended, sagging stomachs with the pylorus some distance above the lowest outline of the stomach. They thus have a mild form of gastropexia. Civilization has made man the controller of machines to do work instead of his doing the work himself. His muscles have lost their tonicity from lack of use, especially the muscles of the abdomen and intestines. The flabbiness of the muscles causes the intestines to sag, and this deprives the stomach of the cushion of intestines on which it normally rests. The stomach is thus compelled to sag too, but the pyloric region is fastened so that it cannot sag. The result is the lagging down of the lower part of the stomach. It is so common that the text books give it as the normal type. He then describes the important information that can be derived from fluoroscopy of the stomach after the patient has ingested a suspension of bismuth in water. The peristalsis can be seen and watched and deviations from normal detected. If the shadow is indented at some point, or if there is a gap anywhere, or the outline is like a picket fence at some part, it

is easy to diagnose a tumor or other anomaly in the stomach wall. If the peristaltic waves stop at a certain point or if the movements are atypical, the information thus obtained is of great importance, especially the finding of insufficiency of the peristalsis in the antrum. It is sometimes easy to palpate foreign body when its shadow can be seen, although palpation before was impossible. Another important finding is the discovery that a palpable tumor, supposed to be in the stomach, lies outside of the stomach shadow. In conclusion he refers to Sahli's desmoid test of the stomach functioning (mentioned in these columns on page 760). He calls attention to the possibility of erroneous conclusions from various eventualities that might arise with this test, but adds that they can be entirely avoided if the little bag is filled with bismuth, instead of a stain, and then watched with the fluoroscope. It is easy to note the exact moment when the little bag opens from the dissolving of the catgut with which it is tied, or the bag, if he found, still tied up, in the small intestine.

46. Anemia and Defective Gastric Juice.—Rollin does not attempt to theorize but merely relates his clinical experience the effect that in patients with insufficient or lacking secret of gastric juice there was always evidence of anemia. In hypochlorhydria the hemoglobin was above normal, and in nervous dyspepsia it was practically normal. Only in the cases ranging from subacute gastritis to gastric achylia was anemia the constant finding. His experience further demonstrated that administration of natural gastric juice from the dog, supply the missing element for gastric digestion, was followed by the subsidence of the anemia. The supplementary gastric juice insured proper nourishment for the elements of blood.

48. Local Anesthesia in Regard to Sensibility of Organ Tissues.—Lennander has long made a study of the sensibility of the different tissues and organs, his conclusions having duly chronicled in THE JOURNAL as they have appeared in 1901. He asserts that if the surgeon will only take the time to induce proper local anesthesia it is possible to perform extensive operations with the minimum of the anesthetic without pain or after effects from the drug. He relates a number of convincing examples from his own experience never surpasses the dose of 3 or 4 cc. of cocaine, using a 1:125 or .25 or .5 per cent. solution, generally the first; two drops of 1 per thousand solution of adrenalin; to each cc. of the cocaine solution. He points out that where skin possesses four kinds of sensibility, to pain, pressure, heat and cold, the muscles and aponeuroses have comparatively little sensibility. Inside the body all the serous and serous coverings over the large cavities of the body and coverings of the bones and joints possess the sense of touch. They probably have no sensibility for pressure, heat and cold, but pulling or stretching them, or pressing them against substance beneath causes pain. On the other hand, the internal organs lack all kinds of sensibility. They are not sensitive to pain, pressure, heat nor cold. He regards this as an established fact in regard to the stomach, intestine, and gall bladder, and almost certain in the brain, thymus, substance, cartilage, lungs, heart (according to several o

ions, the blood vessels when they are isolated from their surrounding connective tissue, the thyroid gland, liver, spleen, pancreas, parenchyma of the kidneys, the female internal genital organs and the serosa-enclosed parts of the testicles. It has hitherto been generally assumed that these internal organs possess little if any sensibility in health, but that they become highly sensitive in case of acute inflammation. Lennander, however, is convinced that the observations here related and his former experiences have shown that this assumption is incorrect. He thinks it is a wise economy that these internal organs are not burdened with sensibility, while their envelopes are extremely sensitive and are thus able to give warning of impending danger and the possibility of warding it off. Injurious influences affecting these internal organs from within could not be thrown off directly, and consequently it would be of no use for them to be subject to sensations of pain, pressure, heat and cold. None of the organs innervated by the sympathetic nerve below the branching of the recurrent nerve possesses any sensibility for pain, pressure, heat or cold. The consequence is that general anesthesia is not required for operations on tissues which are incapable of any sensation of pain. Among the numerous instructive examples cited is one which shows the complete lack of sensibility on the part of the gray and white substance of the brain to the thermocautery, faradization and to various operative measures. The incision in the dura mater was not felt as pain. Another patient had no sensation of pain when the actual cautery was drawn along the side wall of the vagina. In the amputation of the leg of a medical student the incision under cocaine-adrenaline anesthesia was painless down to the layers of the fascia, when few whiffs of ether were given. The operation was concluded without general anesthesia as the bone substance and bone marrow were free from sensibility, and the local anesthesia of the soft parts from the injection of the cocaine lasted until the operation was completed. No constriction was applied to the limb above. The Griggs amputation in this case was done without account of paralysis and atrophy, resulting from poliomyelitis in infancy. The particulars of this expert observation are instructive. In conclusion Lennander comments on the fact that so long as a lesion developing in the spine does not reach on the periosteum, it must develop without causing local symptoms. When pain can be induced at the spot pressing on the spinous process or on the head, this is a sign that the bone has been destroyed so that there is abnormal motion on ligaments and periosteum. Before this sign can be observed evidence of the presence of the lesion might be detected by bending and stretching the trunk and thus exerting traction which will be experienced as pain when the periosteum and ligaments have begun to be affected by toxins, though the process is not yet far enough advanced for cure alone to elicit pain.

Traumatic Aphasia.—In the case described a circumferential injury of the skull was followed by complete aphasia, which was gradually regained as the lesion healed. The report illustrated and adds several points to our knowledge of traumatic disturbances of the speech center.

Liver Abscess.—Goebel's article is a study of tropical abscesses based on 23 cases observed in Egypt. He deems that exploratory puncture is indispensable. In operative cases he prefers local anesthesia. The lesion should be opened wide, and for this purpose he advises resection of about one or two ribs. He cites some instances from his experience to show the disadvantages and danger of too small incisions and inadequate intervention. The dressings should be changed often and the cavity rinsed with salt or boric acid solution. The liver has a tendency to slide upward when its position is reduced. For this reason it is wise to resect a rib above the lesion. In some cases he had to make a secondary incision of a rib above on this account. He sometimes wipes the walls of the cavity with 10 per cent. solution of nitrate. Only 2 of the 23 patients on whom he operated were women. He could not detect that race, malaria, or any other influence on the occurrence of suppuration prevailed. The abscesses perforated into the lungs or bronchi in a number of cases, requiring plastic operations, and the abscesses were frequently multiple. Chloroform should be

avoided on account of the accompanying tendency to fatty degeneration of the liver.

52. Discussion of the Epidemic Nature of Appendicitis.—Rostowzew analyzes a bibliography of 117 references and extensive personal experience to prove that appendicitis is not an epidemic affection and that no connection between it and epidemics of influenza is discoverable.

54. Tumors Encroaching on Spinal Cord.—Oppenheim gives an illustration of five tumors developing on the inner aspect of the spinal dura which he successfully removed in the five cases. The tumors are all of about the same size, round or ovoid in shape. All were diagnosed during life and the exact location determined, with one exception, in which it was located too high. The specimen from a sixth similar case is not included in the illustration. One of the patients has been cured for nearly four years, another for several months to date, another was relieved of all symptoms for a number of months, but the other patients succumbed in a few days or weeks after the operation. If infection could have been prevented, 2 of the latter would probably have been cured like the first patient. He is convinced that the chances of operative treatment are much better for tumors of the spinal membranes than for brain tumors, but the indications must be carefully observed. In a recent case he advised against operating as the diagnosis of the exact location of the tumor was uncertain. Another surgeon performed the operation, which gave no results and was fatal. The details of 8 cases are given. In one the symptoms had been those of a growth encroaching on the spinal cord in the lower dorsal region. It was an extravertebral, malignant neoplasm developing from the seventh rib; it had destroyed the vertebra and made its way into the spinal canal. The preceding stage of neuralgia was probably due to compression of the intercostal nerves. Roentgen examination during the neuralgic stage would have revealed the extravertebral growth, but the patient was not seen until this stage had passed, and the symptomatology later was then merely that of the ordinary benign, intradural tumor. It has been his experience in several instances that these malignant tumors originating in the vicinity of the spine first make their presence manifest when they begin to encroach on the spinal roots and cord. The results of partial removal of the tumor were surprisingly good. The previously decrepit, paralyzed man was able to walk without a cane and to visit his place of business; this improvement persisted for four months. In a second, similar case, the growth was totally removed and the patient is still in good health, eight years afterward. This patient was a woman of 27 who had noticed for four years a lump in her neck, apparently originating in the fourth or fifth cervical vertebra, and becoming increasingly painful. During the last year there was paresis of the arm and leg on that side and numbness in the other leg. The muscles in the region of the cervical plexus were atrophied, and the response to electric tests was abnormal. The tumor proved to be a spindle-shaped enlargement of a nerve root, and it extended into the spinal canal. As the tumor was seen to be a sarcoma the surgeon (Bardleben) regarded it as inoperable, and dismissed the patient. A surgeon in her home town later removed the growth, permanently curing all the pains and tendency to paralysis, although a briefly transient mental disturbance followed the radical operation. Oppenheim urges those who have published cases of successful removal of malignant tumors of this kind to report on the ultimate outcome. The differential points in the symptomatology of Oppenheim's various cases are reviewed and discussed in detail.

56. Appendicitis Larvata.—Korach applies this term to a form of chronic appendicitis which belongs in the category of chronically recurring rather than that of chronic residual appendicitis. He reports 5 cases and describes masked appendicitis as a combination of two factors, namely, a chronic affection of the appendix and a neurosis affecting the viscera. The neurosis usually is the result of hysteria or hysteroneurosthenia. Treatment which cures one of the factors alone but allows the other to persist, is inevitably ineffectual or is liable to aggravate the persisting factor. He classifies this form of appendicitis in the group of the hard-to-cure myxoneuroses, which includes bronchial asthma and mucous colitis.

63. Results of the Prematurely Induced Menopause.—Pollak ascribes to imperfect oxidation of fat the morbid phenomena observed after the anticipated climax. The lack of the internal secretion of the ovary causes a reduction in the oxidation of fat. The unoxidized fat accumulates and overwhelms the parenchymatous organs and also the heart. It is deposited in the muscle fibrils in the heart, interfering with their physiologic function as long as it remains there. These, at least, are the conclusions justified by his extensive experimental research and study of the subject in the clinic and in the literature. The disturbances of the premature menopause, consequently, he thinks, may be regarded as the results of this temporary over-accumulation of fat in the organism.

68. Abdominal Implantation of Uterus.—Rissmann believes that a uterine fistula of long standing is generally accompanied by such changes in the parts that nephrectomy is the best treatment. In case the uterus is to be implanted, he advises cutting the end very slanting. It is then implanted as usual in the wall, and the long pointed tip is drawn up inside and sutured to the wall of the bladder, a short distance from the implantation. This allows the uterus to be firmly sutured without necessity for stitches in the part still serving to carry the urine. Sutures in this part are liable to cause suppurative and to drop through into the lumen, or the stitches may be taken too deep. In either event stenosis of the uterus is liable to follow, all of which is avoided by suturing merely the long sloping end below the point where the intact ureter passes through the bladder wall. The article is illustrated.

71. Suture of Perineum.—Baumm uses a large curved needle and passes it entirely around, outside of the laceration, never allowing it to make its appearance in the wound. The suture thread thus introduced is tied just below the lower end of the laceration. The effect is that the tear is made smaller, all the parts having been compressed together by the thread as it is drawn up and tied. Another thread is then passed around the gap still left, and tied in the same way, and still another after this. The illustrations readily show how these three concentric threads gradually reduce the size of the laceration without leaving a chance for any recesses to form. The small gap then left is sutured like any wound. The walls of the tear in the vagina are brought so close together that they do not require suturing. In case the perineal laceration has included the anus, he first passes a thread entirely around the laceration in the sphincter and anus, inserting the needle at one end of the broken ring formed by the torn anus, and bringing it out at the other end of the ring. When the thread thus inserted is tied, the rest of the laceration is treated as above described.

73. Intrauterine Pneumonia.—A woman presented evidences of croupous pneumonia during the last days of pregnancy and gave birth to a male child exhibiting cyanosis and dyspnea

with findings in the lungs typical of pneumonia. The child died in eleven hours and the pneumococcus was cultivated from the lung tissue. It was not discovered elsewhere in the child's organs.

75. Metastasis in Brain of Uterine Carcinoma.—The tumor in this case was in the left temporal lobe, and was accompanied by much edema and evidences of cerebral hemiplegia. In second case there was metastatic endocarditis, but no brain findings, although the diffuse carcinomatous endocarditis might have favored the spread of cancer elements to the brain.

76. Treatment of Ovarian Tumors in General.—Polano has been studying the latest statistics of various operators in regard to the ultimate results of operations for ovarian tumors. They suggest that women with tumors in the ovaries, even apparently innocent ones, seem to display a tendency to tumor formation in other organs. In case of malignant disease, extragenital organs, the ovaries seem to be the favorite sites for metastatic affections. The symptoms emanating from the ovaries in such a case may easily mask those of the primary growth. He is convinced that when it is necessary to operate on an ovarian tumor of a malignant or dubious nature, it is wise to remove the uterus with both ovaries. In case of bilateral ovarian tumor this should always be done, unless metastases in the peritoneum contraindicate further intervention. Extirpation of the primary tumor and of the cancer ovaries at the same time may be followed by long survival. In von Franqué's case the patient lived six months after section of the stomach and ovariectomy in one sitting. If ovary seems sound he advises leaving it as the removal of sound second ovary is liable in some cases to impair general health very much. The danger of involvement of sound organ is actually not so great as is generally supposed. It can be left in place without concern if it be re-examined from time to time. The majority of European operators seem to prefer the vaginal route in operating on these patients. Ott of St. Petersburg has a record of more than 20 vaginal ovariectomies. Polano's conclusions are based mainly on the reports and discussions at the German Congress of Gynecology last year. The ultimate results were better in cases of sarcoma than of carcinoma, and poorest in case of papilloma.

81. Veronal Poisoning.—Kress reports symptoms of poisoning in 3 out of 12 neurasthenic patients to whom he has been giving veronal. The dose was .5 gm. veronal on an empty stomach. A cumulative action was apparent by the third or fourth day. Extreme somnolence, inability to get up out of bed, or proper food were the main symptoms.

84. Atropin in Gynecology.—Drenkhahn expresses the opinion that greater use is not made in gynecology of the power of atropin to relax the muscles and to hold them relaxed. In case of a wound infection of the uterus, and if the infection can be kept still the infection remains localized and heals. Atropin, he thinks, is an ideal drug for the treatment of holding the uterus still. He thinks that the content of the uterus entail toxemia and bacteremia from this. Even in case other organs are already affected the

is useful as it checks the absorption of toxic substances from the surface of the puerperal uterus. It relates a few examples from his experiences to show the benefit from atropin in not too far advanced puerperal fever. The only by-effect noted besides the disturbance in accommodation, was the occasional paralysis of the bladder. Catheterization should not be deferred too long. The patients do not perceive that the bladder is distended. The dosage recommended by Drenkhahn is from 12 drops of a 1 per thousand solution of atropin three times a day, to 20 drops every six hours. He kept this up in the case he describes in detail for nine days, giving a total of .06 gm. of atropin, that is, about .006 gm. a day, fully twice the maximum dose. Although the puerperal fever was severe the patient recovered in two weeks without other treatment.

07. Hypertrophy of Heart in Nephritis.—Katzenstein found that the blood pressure was not raised in his experiments on rabbits when the renal artery or pedicle of the kidney was ligated. In some instances the pressure was lowered, the other hand the pressure was decidedly increased when kidney was not tied off but was left in communication with the general circulation, although with some obstruction to the normal circulation through the kidneys. When the tie was only slightly twisted or when a ligature was tied very loosely to the renal artery, the result of this obstruction to the circulation was a decided increase in the blood pressure, persisting for hours. He does not attempt to explain this remarkable difference in the results when the circulation through the kidneys was merely obstructed or cut altogether.

00. Histologic Study of Paraffin Injections.—Kirschner's researches demonstrate that paraffin injected into the tissues is absorbed like catgut, nor does it become encapsulated, like a foreign body. Connective tissue grows into and through both the soft and hard paraffin with the ultimate absorption of the injected foreign body. A number of examples are related. The organization of the paraffin proceeded with much more activity in some patients than in others, probably from the high pressure on the tissues in the different cases.

130. Determination in Urine of Bodies Resembling Albumoses.—Fittipaldi adds 5 drops of a saturated solution of trichloroacetic acid to 5 c.c. of urine and heats to boiling, then sets aside for five or six hours. The precipitate may contain albumin alone or mixed with nucleoalbumin, or albumosoids may be present. To determine the presence of the latter the supernatant fluid is decanted, filtered and treated with mercuric iodid and potassium. If the fluid becomes turbid this is due to the presence of albumosoids unless it can be explained by the presence of an alkaloid (quinin). The precipitate is suspended in alcohol and centrifugated. The alcohol is then expelled and the precipitate is dissolved with the minimum of caustic soda at 31 to 32 per cent. In another test tube a mixture of 0.5 c.c. of a 5 per cent. solution of nickel sulphate with the same amount of ammonia is shaken up and poured out. The alkaline solution of the precipitate is then poured into the same tube. If it contains albumosoids the fluid turns an orange tint. To make the test still more exact 25 c.c. of urine can be precipitated with six times the amount of absolute alcohol. The alcohol is then decanted and the precipitate is examined as above. With this technique all the proteid substances are retained in the precipitate and the test is more exact.

132. Operative Treatment of Stab Wounds of the Thorax.—Gangitano discusses 3 personally observed cases of stab wounds of the chest, and such injuries in general. His conclusions

are all in favor of prompt surgical intervention. It is the only means, he thinks, of locating the cause of the hemorrhage and of checking it. Wide opening up of the chest is not such a dangerous procedure, he is convinced, as is generally assumed. It should be done with greater confidence and not merely as a last resort. It is an easy matter to suture a stab wound of the lung, and this effectually arrests the hemorrhage.

136. Fixation of Kidney.—Biondi has had occasion to perform nephropexy in 45 cases, and early became convinced that the various techniques proposed to date have each some serious disadvantage. He devised a method which he has successfully applied in a number of cases and commends as being entirely harmless, fastening the kidney securely and permanently, while not injuring the renal tissue. He removes the fatty and fibrous capsule of the kidney, and then holds the organ in its place by packing with a long strip of gauze. The gauze is packed to fill all the space in front of and below the kidney. He first passes a strip of gauze around the lower pole of the kidney; an assistant pulling on the ends of this strip of gauze raises and holds the kidney in place. He then sutures the end of the long strip of gauze to the center of this first loop of gauze, and the rest of the long strip is packed in place, filling the space in front of the kidney with zigzag folds and then the space below the lower pole, bringing the end of the strip out through the lower angle of the incision. The two ends of the first loop of gauze are brought out through the upper angle of the incision. The most energetic tamponing never produced any disturbance in the kidney or adjacent organs. After eight or ten days he commences to withdraw the gauze, a little at a time, and the kidney is invariably found firmly fastened in its place. No disturbance with function has ever been noted, not even in two women who were treated by this technique, both kidneys being thus fastened in place in a single sitting. The results were equally good in the case of a male patient whose left kidney had been fastened in place in this way. One month later the right kidney had to be removed, six months after nephrotomy had been done on this kidney for calculi. In numerous experiments on dogs he found the results equally satisfactory when one kidney was removed and the other packed in place in this way with the tampon. The new formation of connective tissue was not very extensive; it did not invade the tissue of the gland, and caused neither anatomic nor functional disturbances. The adhesions holding the kidney in place were evident by the fourth day, and reached their maximum by the twentieth day. After this the adhesions loosened up a little, which allowed the kidney its physiologic excursions with the movements of the diaphragm, as in normal conditions.

137. Experimental Study of Rabies.—Fermi remarks that the rabbit, guinea-pig, dog and cat are almost totally insensible to hypodermic injection of fixed rabies virus, but that rats are especially susceptible. He describes numerous experiments undertaken to solve various problems of treatment of hydrophobia. In his attempts to produce a Pasteur vaccine that will keep indefinitely he found that a number of mercury and silver salts were able to keep the emulsion sterile in his tests, as also 1 per cent. carbolic acid and 1 per cent. malachite green.

140. Effect on Heart and Kidneys of Bandaging the Legs.—Plessi has been making a number of tests of healthy persons and of those with other than vascular affections to determine the effect of blood-expelling bandaging of the legs. The subjects were kept in bed twenty-four hours and the pulse, blood pressure and urinary findings recorded. Then later they stayed in bed for another twenty-four hours or longer after a bandage had been wound around each leg from the sole to the groin. Comparison of the findings showed a remarkable effect on the kidney functioning. The amount of urine increased from 50 to 100 per cent. or more. The specific gravity of the urine, the pulse and the blood pressure did not show any appreciable difference, although the elimination of chlorids was increased. The bandages were tolerated without any disturbance by healthy subjects, but they had to be removed in six and seven hours in the case of one patient with mitral stenosis and of another with polyserositis, on account of the development of precordial oppression and palpitation. Even in this brief

space of time the diuresis was considerably augmented in each case. This effect is probably the result of the active hyperemia in the kidneys.

143. Antidiphtheria Serum in Erysipelas.—Mastri reports from Rome 3 cases of erysipelas which seemed to be cut short or very favorably influenced by two injections of antidiphtheria serum. He injected 500 units in children and 1,000 in a man of 60 and a woman of 35, repeating the injections twice in the course of one or two days.

147. Gastropexy.—Lafranchi has coined this term from the Greek to apply to an operation by which the stomach is made smaller by a series of threads passed nearly parallel through its outer coat from the upper to the lower margin of the organ on the anterior aspect. Drawing up the thread makes the organ smaller. Instead of "taking up a tuck" as by the usual technique for such operations, the organ is "shirred." This technique interferes less with the tonicity and peristalsis of the stomach, while it leaves the pylorus intact. The outcome was extremely satisfactory in the case of a man of 3 whose chronically dilated stomach extended four fingerbreadths below the umbilicus.

150. Preventive and Curative Use of Antitetanus Serum.—Pergola relates experiences with 30 patients who were given prophylactic injections of antitetanus serum, and also with 2 patients already presenting evidences of tetanus. He states that the action of the serum is especially pronounced when the disease runs a protracted course. He found that the prognosis was more favorable the longer the period of incubation. The intracerebral or intravenous use of the serum did not appear to have any advantages over the subcutaneous route. In conclusion he adds that between 1887 and 1902 an average of 750 persons died annually of tetanus in Italy. In the last few years it has become much less frequent, and his annual material of about 1,800 patients he has not encountered a case except the two mentioned above with tetanus already under way when first seen.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sent them. A selection from these volumes will be made for review dictated by their merits, or in the interests of our readers.

SELF-PROPELLED VEHICLES. A Practical Treatise on the The Construction, Operation, Care and Management of all Forms of Automobiles. By J. E. Homan, A.M., with Upward of 500 Illustrations and Diagrams. Giving the Essential Details of Construction and Many Important Points on the Successful Operation of the Various Types of Motor Carriages Driven by Steam, Gas and Electricity. Cloth. Pp. 652. Price, \$2.00. New York: T. A. DeLacy & Co., 1905-1906.

CASE TEACHING IN MEDICINE. A Series of Graded Exercises in the Differential Diagnosis, Prognosis and Treatment of A. Cases of Disease. By R. C. Cahot, A.M., M.D., Instructor in Medicine in the Harvard Medical School and Physician to Patients at the Massachusetts General Hospital. Cloth. Pp. Price, \$1.50. Boston: D. C. Heath & Co., 1906.

RECENT ADVANCES IN PHYSIOLOGY AND BIO-CHEMISTRY. Edited by Leonard Hill, M.B., F.R.S. Contributors: B. Moore, M.A., J. J. R. Macleod, M.B., L. Hill, M.B., F.R.S., M. S. Pembrey, A. Macleod, A. P. Reid, M.A., M.D., with Diagrams. Cloth. 740 pp. Price, \$5.00 net. New York: Longmans, Green & Co., 1906.

PROFESSIONAL EDUCATION, with Special Reference to Medical Address. Delivered at King's College, London, on Oct. 3, 1905. By T. C. Allbutt, M.A., M.D., F.R.S., Regius Professor of Medicine in the University of Cambridge. Cloth. Pp. 80. Price, 75 New York: The Macmillan Co., 1906.

PHARMACOLOGY AND THERAPEUTICS. By R. W. Wilcox, M.D., LL.D. Sixth Edition. Based on the Fifth Edition of and Wilcox's "Materia Medica and Therapeutics." Cloth. Pp. 1010. Price, \$3.50. Philadelphia: P. Blakiston's Son & Co., 1906.

CHEMISTRY OF THE PROTEIDS. By G. Mann, M.D., B.Sc., formerly Demonstrator of Physiology, Oxford. Based on Prof. G. Mann's "Lehrbuch der Eiweiss-Chemie." Cloth. Pp. 604. \$2.25. New York: The Macmillan Co., 1906.

DIE NIERENERKENNUNG. Ihre Ursachen und Bekämpfung. G. verständliche Darstellung von Dr. H. Enzel, Kurarzt in J. (Augsburg), Mit einer Abbildung im Text. Paper. Pp. 50. M. Verlag der Aerztl. Rundschau. 1906.

RADIUM UND RADIOAKTIVITÄT. von Dr. med. Ernst Sommer. Inhalt für physikalische Therapie. Winterthur (Schweiz) Mit Abbildung im Text. Paper. Pp. 52. Munich: Verlag der Ichen Rundschau. 1906.
